The Synthesis of Indigotindisulphonic Acid (Indigo-carmin). By R. KNIERSCH (*Ber.*, 24, 2086—2089).—Previous to the publication of Heymann's synthesis (this vol., p. 1069), the author had also observed that phenylglycocine is converted by fuming sulphuric acid into indigo-carmin; he differs, however, from Heymann with regard to the manner in which the reaction takes place. The latter supposes the formation as an intermediate product of an indoxyl sulphate, which then undergoes oxidation at the expense of the sulphuric anhydride present, whereas the author believes that the reaction proceeds in the same manner as in Heumann's synthesis with caustic potash and phenylglycocol, the elements of water being withdrawn from the latter, with formation of a leuco-compound (and in this case with simultaneous sulphonation), and that the leuco-compound is then oxidised by the oxygen of the air. The first product, like the leuco-compound obtained with caustic potash, is very unstable in acid solution; the oxidation only takes place when all free sulphuric anhydride has disappeared, and that it is really the oxygen of the air which causes this oxidation is confirmed by the fact that the surface of the mass formed in the reaction becomes blue on exposure, and that if the sulphuric acid added as a diluent is previously aërated, the yield of indigo-carmin is increased. The formation of sulphurous anhydride is readily accounted for by the subsidiary reactions which take place even under the most favourable conditions.

H. G. C.

Action of Stannous Chloride on Nitrophenylindazole-carboxylic Acid. By L. SCHULHOFFER (*Annalen*, 264, 149—152).—A compound of the composition $C_{14}H_{11}N_3O_4$ is formed when finely-divided nitrophenylindazolecarboxylic acid (compare Meyer, *Abstr.*, 1889, 516) is heated with excess of an alcoholic solution of stannous chloride, and the diluted solution treated with hydrogen sulphide, filtered, and evaporated. It crystallises from hot water in colourless needles, melts at 235° , decomposes at 240° , and is soluble in acetic acid; its constitution is possibly expressed by the formula

F. S. K.

Benzidine Colouring Matters. By R. BRASCH and G. FREYSS (*Ber.*, 24, 1958—1966).—Dimethoxydimethylbenzidine

is prepared from nitromethoxytoluene [$\text{Me} : \text{NO}_2 : \text{OMe} = 1 : 2 : 4$] by reduction in the usual way. The metanitroparacresol required is obtained by dissolving 375 grams of paratoluidine in a warm mixture of 465 grams of 52 per cent. nitric acid and 1900 grams of water, cooling, adding a second 465 grams of the acid, diazotising the crystalline magma below 10° with a solution of 243 grams of sodium nitrite in 500 grams of water, and afterwards carefully warming in a reflux apparatus until the decomposition is completed. Under these

conditions, the yield amounts to 78 per cent. of the theoretical. The product contains a small proportion of dinitrocresol, but this can readily be separated after methylation since nitromethoxytoluene is volatile with steam whilst dinitromethoxytoluene is not.

Azopyparamethoxytoluene, $C_{16}H_{18}N_2O_4$, is formed when metanitroparamethoxytoluene dissolved in methyl alcohol is heated with the theoretical quantity of sodium methoxide on a water-bath for 48 hours. It crystallises from methyl alcohol in compact, sulphur-yellow prisms, melts at $148-149^\circ$, and is readily soluble in benzene, alcohol, and acetic acid.

Azoparamethoxytoluene, $C_{16}H_{18}N_2O_2$, is prepared by reducing metanitroparamethoxytoluene either in 10 per cent. methyl alcohol solution with an excess of 5 per cent. sodium amalgam, or, preferably, with the calculated quantity of stannous chloride and aqueous soda (compare Witt, Abstr., 1886, 145). It can also be obtained by adding the calculated quantity of diazotised metamidoparamethoxytoluene to a strongly alkaline solution of paracresol and methylating the resulting azo-compound. It crystallises in large, well-formed scarlet-red prisms, melts at $178-179^\circ$, is sparingly soluble in alcohol, readily soluble in acetic acid, chloroform, and benzene, and on reduction with a considerable excess of sodium amalgam is converted into metamidoparamethoxytoluene.

Orthodimethoxymetatolidine,

[Me : NH_2 : OMe = 2 : 4 : 5], is prepared by adding the calculated quantity of stannous chloride to a hot, hydrochloric acid solution of the azo-compound. It crystallises in silvery-white scales, melts at $156-157^\circ$, and dissolves slightly in water, but very readily in alcohol. When diazotised, it yields with β -naphtholdisulphonic acid-R, α -naphthol- α -sulphonic acid and naphthionic acid dyes which vary in shade from violet-red to red, and are almost destitute of affinity for unmordanted cotton. These results are of interest, since the tetrazo-colouring matters derived from orthodimethoxymetanisidine, like those from orthanisisidine, are direct cotton dyes, whilst those from orthodimethylmetatolidine have but little affinity for unmordanted cotton (Noelting and Stricker, *Der.*, 21, 3138). W. P. W.

Anilidoacridines and Hydroxyacridines. By E. BLSIHOHN and W. CURTMAN (*Ber.*, 24, 2039-2048).—In Bernthsen's synthesis of acridine derivatives (Abstr., 1864, 1356), diphenylamine,

is acted on by formic acid in presence of zinc chloride, with formation of acridine, $C_6H_4 \cdot \begin{smallmatrix} N \\ | \\ CH \end{smallmatrix} > C_6H_4$. The authors treated diphenylmetadiamidobenzene, $C_6H_5 \cdot NH \cdot C_6H_4 \cdot NH \cdot C_6H_5$, in a similar manner, hoping to obtain a double acridine of the formula

They find, however, that only one anilido-group takes part in the reaction, and that an anilidoacridine having the constitution

is formed. Similar compounds containing an alkyl group in the meso-position may be obtained by substituting other acids for formic acid, and all these compounds when treated with hydrochloric acid under pressure yield the corresponding hydroxy-derivatives. Whether the anilido- and hydroxy-groups occupy the ortho- or para-position to the methenyl group in the central nucleus has not yet been proved.

To prepare *anilidoacridine*, $\text{C}_{15}\text{H}_{14}\text{N}_2$, diphenylmetadiamidobenzene (5 grams), zinc chloride (10 grams), and 90 per cent. formic acid (5 grams) are heated for 4—5 hours at 250° . The product is dissolved in hot alcohol, the latter almost completely evaporated, and the residue poured into water. The red flakes which separate are warmed with very dilute sulphuric acid, and filtered from resinous matter; the sulphate separates out on cooling, and is treated with aqueous soda, extracted with ether, the extract dried with potash, evaporated, and the residue recrystallised from toluene. It forms compact, brownish-red, flat needles, melts at 175 — 176° , and is fairly soluble in alcohol, less readily in ether, benzene, and toluene. Its salts with mineral acids are red, and are easily soluble in alcohol, less readily in water, and almost insoluble in concentrated acids.

Hydroxyacridine, $\text{C}_6\text{H}_4 < \begin{array}{c} \text{N} \\ | \\ \text{CH} \end{array} > \text{C}_6\text{H}_5 \cdot \text{OH}$, is prepared from the foregoing compound by heating it with hydrochloric acid at 250° . The solution is made alkaline, separated from aniline by distilling in a current of steam, filtered, and treated with hydrochloric acid. The *hydrochloride* forms small, brownish-yellow needles, and when boiled with a solution of sodium carbonate yields the free hydroxyacridine in yellow, microscopic needles melting at 250° . It forms readily soluble salts with both mineral acids and alkalis, and is reduced to acridine by heating with zinc-dust.

Anilidomethylacridine, $\text{C}_6\text{H}_4 < \begin{array}{c} \text{N} \\ | \\ \text{CMe} \end{array} > \text{C}_6\text{H}_5 \cdot \text{NHPh}$.—To prepare this compound it is best to convert the diphenylmetadiamidobenzene into the diacetyl compound and treat the latter with zinc chloride. It is purified in a similar manner to the anilidoacridine, and crystallises from toluene in fascicular aggregates of brownish-red needles, melts at 215 — 216° , and is readily soluble in methyl alcohol and ethyl alcohol, sparingly in ether and benzene. The corresponding *hydroxy-methylacridine*, $\text{C}_{15}\text{H}_{13}\text{MeN} \cdot \text{OH}$, crystallises in microscopic, red needles and melts at 250° ; its *hydrochloride*, $\text{C}_{15}\text{NH}_7\text{Me} \cdot \text{OH} \cdot \text{HCl} + \text{H}_2\text{O}$, forms beautiful yellow needles.

Anilidophenylacridine, $\text{C}_6\text{H}_4 < \begin{array}{c} \text{N} \\ | \\ \text{CPh} \end{array} > \text{C}_6\text{H}_5 \cdot \text{NHPh}$, is obtained from dibenzoyldiphenylmetadiamidobenzene by heating it with zinc chloride, and also crystallises from toluene in fascicular aggregates of brownish-

red needles. It melts at 156—197°, and dissolves readily in alcohol, ether, and benzene, the dilute, ethereal solution showing a greenish fluorescence. The corresponding *hydroxyphenylacridine*, $C_{11}NH_7Ph \cdot OH$, is a red, microcrystalline powder; its *hydrochloride*, $C_{11}H_7NO \cdot HCl$, forms very lustrous, golden-yellow plates, and the *sodium* salt crystallises in a like manner.

Anilidonacridylbenzoic acid, $N \begin{array}{c} \text{C}_6H_5(NHPh) \\ \text{C}_6H_4 \end{array} > C \cdot C_6H_4 \cdot COOH$, is obtained by simply heating together phthalic anhydride and diphenylmetadiamidobenzene without addition of zinc chloride. It forms small, red crystals, and is almost insoluble in the usual solvents, with the exception of acetic acid. It melts above 300°, and yields salts with mineral acids which are almost insoluble in water, but may be recrystallised from absolute alcohol. Its *sodium* salt forms white, glistening plates. When heated with hydrochloric acid at 250°, it yields *hydroxyacridylbenzoic acid*, $C_{13}NH_7(OH) \cdot C_6H_4 \cdot COOH$, which melts above 250°, and has a weak basic character, forming salts which are dissociated by boiling water. Its salts with alkalis are soluble in water, the solutions showing a slight greenish fluorescence.

H. G. C.

Diphenylene Oxide. By P. GALEWSKY (*Annalen*, 264, 187—193).—*Acetyldiphenylene oxide*, $\begin{array}{c} C_6H_5 \\ | \\ C_6H_4 \\ | \\ C_6H_5 \end{array} > O$, can be obtained by gradually adding aluminium chloride to a carbon bisulphide solution of diphenylene oxide and acetic chloride; it crystallises from dilute alcohol in long, colourless needles, melts at 80—81°, boils above 350°, and is readily soluble in alcohol, ether, chloroform, light petroleum, benzene, and glacial acetic acid, but insoluble in water. The *oxime*, $C_{14}H_{11}NO_2$, crystallises from alcohol in nacreous plates or needles, melts at 145—146°, and is readily soluble in most ordinary solvents except water, in which it is insoluble. The *hydrazone*, $C_{20}H_{16}N_2O$, separates from alcohol in yellowish-brown prisms, melts at 132—133° with decomposition, and is soluble in alcohol, ether, &c., but insoluble in water.

Diamidophenylene oxide, $\begin{array}{c} C_6H_3(NH_2) \\ | \\ C_6H_3(NH_2) \end{array} > O$, crystallises from alcohol in yellow needles and melts at 188°; the *acetyl* derivative is a colourless, crystalline compound, and does not melt when heated at 320°.

F. S. K.

Condensation of Benzaldehyde with Phenols. By A. RUNAKOFF (*Chem. Centr.*, 1891, i. 662; from *Bull. Acad. St. Pétersbourg*, 33, 461—468).—The author finds that benzaldehyde forms condensation products with phenols in accordance with Baeyer's general reaction, 2 mols. of phenol and 1 mol. of aldehyde condensing with loss of 1 mol. of water. The following compounds are described:—

Paradihydroxytriphenylmethane, $CHPh(C_6H_4 \cdot OH)_2$, is prepared by adding 10 grams of benzaldehyde and 17.8 grams of phenol gradually to 1—2 c.c. of sulphuric acid (4:1 vol. H_2O), and after allowing the mixture to cool 3—4 c.c. of the sulphuric acid is added. After

remaining for several hours, the mixture is poured into water, filtered, the precipitate washed with hot water, any unchanged benzaldehyde or phenol is separated by distillation with steam, the precipitate washed with benzene, crystallised from dilute acetic acid, dissolved in alcohol, and reprecipitated by water. It crystallises in needles, melts at 160—161°, is nearly insoluble in light petroleum and carbon bisulphide, readily soluble in hot benzene, alcohol, glacial acetic acid, and chloroform, and is identical with O. Fischer and Döbner's compound. If it is warmed with bromine water, the product dissolved in alcohol, and soda solution added, a blue coloration is produced. The *diacetate*, prepared by means of anhydrous acetic acid and sodium acetate, crystallises from acetone in rhombic plates, and melts at 110—111°. The *dibenzoate*, prepared by means of benzoic chloride, crystallises in microscopic, rhombic plates, and melt at 129—130°. It is sparingly soluble in alcohol, readily soluble in ether.

Dinitrodihydroxytriphenylmethane, $C_{18}H_{12}(NO_2)_2(OH)_2$, is prepared by the action of nitric acid, sp. gr. 1.5, in glacial acetic acid solution. It crystallises from alcohol in needles, melting at 133—134°.

Phenyldithymolmethane, $CHPh(C_{10}H_{13}OH)_2$, prepared from benzaldehyde, thymol, and sulphuric acid, melts at 165.5—166.5°. It crystallises from alcohol and benzene with 1 mol. of the solvent, which again separates on drying. With bromine water, alcohol, and potash, it gives a blue colour reaction similar to that obtained with dihydroxytriphenylmethane. The *diacetate* is soluble in alcohol, readily soluble in chloroform and benzene, and melts at 125—126°.

J. W. L.

Oximes of Asymmetrical Ketones. By A. SCHÄFFER (*Annalen*, 264, 152—160).—Various asymmetrical ketones and ketonic acids have been investigated for the purpose of determining whether their oximido-derivatives exist in two isomeric modifications; it has been found that pyruvic acid, levulinic acid, acetophenone, and methyl-deoxybenzoïn yield only one oxime, whereas parabromobenzophenone and paramethoxybenzophenone form two. Two methods were employed for preparing the oximes; in the one the compound was treated with hydroxylamine hydrochloride in dilute alcoholic solution; in the other, the reaction was carried out in presence of excess of soda. The behaviour of the oximes with Beckmann's mixture, and on heating with absolute alcohol at 160—170°, was also investigated.

Two oximes of the composition $C_{13}H_{10}NOBr$ are formed when a dilute alcoholic solution of parabromobenzophenone (1 mol.), hydroxylamine hydrochloride (3 mols.), and sodium hydroxide (9 mols.) is kept at the ordinary temperature until the addition of soda to a small portion of the diluted solution produces no turbidity; the two compounds can be separated by fractional crystallisation from alcohol or by the method described by V. Meyer (this vol., p. 1181).

The one melts at 165—166°, crystallises from dilute alcohol in colourless needles, and is completely decomposed by concentrated hydrochloric acid at 100°; when treated with Beckmann's mixture, it yields the anilide of parabromobenzoic acid. The *acetyl* derivative, $C_{15}H_{12}O_2NBr$, is a crystalline compound melting at 160.5°. The

benzyl derivative, $C_{20}H_{18}ONBr$, prepared by treating the oxime with sodium ethoxide and benzyl chloride in alcoholic solution, melts at $89-90^{\circ}$, and is decomposed by hydriodic acid with elimination of benzyl iodide.

The second isomeride sinters together at 107° , melts at $110-111^{\circ}$, and crystallises from dilute alcohol in needles; it is much more readily soluble than the oxime just described, and, like the latter, it is completely decomposed by hydrochloric acid. When heated with alcohol, it is more or less completely converted into the isomeride according to the duration of the process, but it is not changed by passing hydrogen chloride into its ethereal solution. The *acetyl* derivative is crystalline, and melts at 121° . The *benzyl* derivative separates from alcohol in crystals, melts at $99-100^{\circ}$, and is decomposed by hydriodic acid with elimination of benzyl iodide.

The two isomeric oximes of paramethoxybenzophenone were obtained in like manner; they have recently been described by Hantzsch (this vol., p. 445).
F. S. K.

Oximes of Halogenated Benzophenones. By E. HOFFMANN (*Annalen*, 264, 160-169).—The metadibromobenzophenone obtained by brominating benzophenone (Demuth and Dittrich, this vol., p. 314) is a symmetrical compound and forms only one oxime.

Paradibromobenzophenone, $C_{13}H_8Br_2O$, prepared by treating a carbon bisulphide solution of bromobenzene with parabromobenzoic chloride in presence of aluminium chloride, separates from alcohol in colourless plates, melts at $172-173^{\circ}$, and is readily soluble in ether. When treated with hydroxylamine under various conditions, it yields only one *oxime*; this compound separates from dilute alcohol in slender needles, sinters together at 142° , melts completely at $149-150^{\circ}$, and has the composition $C_{13}H_8Br_2NO$.

Paradiiodobenzophenone, $C_{13}H_8I_2O$, is formed in small quantities when a carbon bisulphide solution of paraiodobenzoic chloride is treated with iodobenzene in presence of aluminium chloride; it crystallises from alcohol in yellowish plates and melts at $233-234^{\circ}$. It forms only one *oxime*, $C_{13}H_8I_2NO$, which crystallises from alcohol in slender needles and melts at $171-173^{\circ}$.

Iodobenzophenone, $C_{13}H_8IO$, prepared by treating benzene with iodobenzoic chloride (m. p. $77-78^{\circ}$) in presence of aluminium chloride, separates from alcohol in crystals melting at $102-103^{\circ}$; when treated with hydroxylamine in alkaline solution at the ordinary temperature, it yields two isomeric oximes of the composition $C_{13}H_{10}INO$: the one crystallises in plates, is sparingly soluble in alcohol, and melts at 178° ; the other crystallises in needles, is more readily soluble, and melts at $132-134^{\circ}$; the latter is converted into the former when it is heated for about 12 hours at 145° .

F. S. K.

Metabromobenzophenone and its Oximes. By W. KOTTENHAHN (*Annalen*, 264, 170-174).—*Metabromobenzophenone*, $C_6H_4BrCOPh$, can be prepared by treating metabromobenzoic chloride with benzene in presence of aluminium chloride; it crystallises from dilute alcohol in needles and melts at 77° .

Two isomeric *oximes*, of the constitution $C_6H_4Br \cdot CPh \cdot N \cdot OH$, are formed when metabromobenzophenone is treated with hydroxylamine in alkaline solution at the ordinary temperature; on diluting with a large volume of water, the α -oxime is deposited, whilst the β -compound remains in solution and can be precipitated with hydrochloric acid.

The α -oxime crystallises in colourless prisms, melts at 168° , and is decomposed into hydroxylamine and metabromobenzophenone by concentrated hydrochloric acid; when treated with Beckmann's reagent, it is converted into *metabromobenzanilide*, a colourless, crystalline compound melting at 137° . Its *acetyl* derivative,

melts at 89.5° , and its *benzyl* derivative at 73° .

The β -oxime forms large, yellow, cubic crystals, melts at 134° , and, like the α -compound, is decomposed by concentrated hydrochloric acid; when heated at about 150° for two days, it is almost completely converted into the α -oxime, and on treatment with Beckmann's mixture it is transformed into *benzoylmetabromanilide*, a crystalline compound which melts at 120° . Its *acetyl* derivative melts at $78-79^\circ$; its *benzyl* derivative crystallises from alcohol in slender needles, melts at 77° , and, like the corresponding derivative of the α -oxime, is decomposed by hydriodic acid with elimination of benzyl iodide.

F. S. K.

Symmetrical Paradichlorobenzophenone and its Oxime. By M. DITTRICH (*Annalen*, 264, 174—178; compare Demuth and Dittrich, this vol., p. 315).—Symmetrical paradichlorobenzophenone, $C_{12}H_8Cl_2$, is best prepared by gradually adding a mixture of chlorobenzene and chlorobenzoyl chloride (m. p. 16°) to warm carbon bisulphide containing aluminium chloride in suspension, and then heating the whole for about two days; it crystallises from alcohol in thin, colourless plates melting at $144-145^\circ$. The *oxime*, $C_{12}H_8NOCl_2$, crystallises from alcohol in small needles, sinters together at 133° , melts at 135° , and is only moderately easily soluble in alcohol and sparingly in alkalis; when heated with concentrated sulphuric acid at 100° , it is transformed into *parachlorobenzoylparachloranilide*, $C_{12}H_8NOCl_2$, which crystallises from alcohol in thin plates melting at $207-208^\circ$. An isomeride of this oxime could not be obtained.

F. S. K.

Diphenylfurazan and some Derivatives of Oximes. By F. D. DODGE (*Annalen*, 264, 178—187).—Diphenylfurazan, prepared by heating α -benziledioxime with water at $200-210^\circ$ (compare Meyer and Auwers, *Abstr.*, 1888, 597), melts at 94° , and distils with partial decomposition, yielding benzonitrile, phenylcarbimide, and a compound melting at 114° , which is in all probability dibenzoylazoxime, identical with the substance obtained by Beckmann by the action of sulphuric acid on α -benziledioxime.

A *dinitro*-compound, of the composition $C_{14}H_4N_2O(NO_2)_2$, is obtained, together with a substance melting at 132° , when diphenylfurazan is treated with a mixture of concentrated sulphuric acid and

fuming nitric acid; it separates from glacial acetic acid in colourless crystals and melts at 218—220°.

An energetic reaction takes place when α -benziledioxime is heated with phosphorus pentasulphide; benzonitrile and small quantities of dibenzoylazoxime are formed, but diphenylfurazan is not produced. When phosphorus pentasulphide is added to a warm benzene solution of benzophenone oxime, a very energetic reaction ensues and thio-benzanilide (m. p. 101—102°) is formed.

Ammonium thiophosphate, $\text{ONH}_4 \cdot \text{PS}(\text{OH})_2$, is deposited in yellow crystals, mixed with sulphur, when acetoxime is treated with phosphorus pentasulphide in carbon bisulphide solution, the insoluble product extracted with alcohol, and the alcoholic solution heated to boiling; it separates from cold water in large, transparent, seemingly monoclinic prisms, melts at 146—150° with decomposition, and is readily soluble in water, but only sparingly in alcohol, and insoluble in ether and carbon bisulphide. It decomposes carbonates, gives a colourless precipitate with lead acetate, and is decomposed by hot dilute nitric acid with separation of sulphur and formation of phosphoric acid; it is also decomposed by mercuric oxide, the filtrate from the precipitated mercury sulphide giving all the reactions of phosphoric acid. F. S. K.

Tolynaphthyl Sulphides. By E. BOURGEOIS (*Ber.*, 24, 2264—2267).—The method of preparation consists in heating the bromotoluene with the lead salt of naphthyl mercaptan at 225° for six hours. The mixture is allowed to cool, extracted with ether, the ether evaporated off, and the product fractionally distilled in a vacuum.

Paratolyl- β -naphthyl sulphide, $\text{C}_6\text{H}_4\text{Me} \cdot \text{S} \cdot \text{C}_{10}\text{H}_7$, crystallises from dilute alcohol in small, nacreous leaflets, melts at 70·5°, boils at 237·5° under 12 mm. pressure, and is easily soluble in ether and carbon bisulphide, sparingly in alcohol.

Paratolyl- α -naphthyl sulphide crystallises from alcohol in beautiful, lustrous, clinorhombic crystals, melts at 40·5°, and boils at 233° under 12 mm. pressure.

Metatolyl- β -naphthyl sulphide crystallises from dilute alcohol in small, white needles, melts at 60°, boils at 236° under 12 mm. pressure, and is easily soluble in ether, carbon bisulphide, and acetic acid, sparingly in alcohol.

Metatolyl- α -naphthyl sulphide is a yellow, refractive oil, and boils at 229·5—230° under 12 mm. pressure.

Orthotolyl- β -naphthyl sulphide is a viscous, yellow, highly refractive oil, and boils at 232° under 12 mm. pressure.

Orthotolyl- α -naphthyl sulphide is an oil similar to the ortho- β -derivative, and boils at 231° under 12 mm. pressure. E. C. R.

Ethyl- α -naphthylamine. By E. BAMBERGER and C. GOLDSCHMIDT (*Ber.*, 24, 2469—2472).—Ethyl- α -naphthylamine reacts in the normal way with diazo-compounds, forming azo-colours, which, on reduction with stannous chloride in hydrochloric acid solution, yield the base originally diazotised and ethyl-1:4-naphthylenediamine. Phenylazo-

ethyl- α -naphthylamine has the properties described by Bicker (this vol., p. 470). *Sulphophenylazoethyl- α -naphthylamine* is a dark, carmine-red, crystalline powder of green metallic lustre, which dissolves in alcohol with a deep-red colour, in concentrated sulphuric acid with a violet colour, and in alkalis with an orange-red colour; the sodium salt, $C_{15}H_{16}N_2 \cdot SO_3Na$, is crystalline.

Ethyl-1 : 4-naphthylenediamine hydrochloride, $C_{12}H_{14}N_2 \cdot 2HCl$, crystallises in flat, silvery needles, melts above 300° , becomes greenish on exposure to air, and is very soluble in water, sparingly soluble in concentrated hydrochloric acid. The base forms colourless, oily drops, having an odour of crude α -naphthylamine, is readily soluble in hot water and the ordinary solvents, and on exposure to air and light rapidly becomes dark in colour. On treatment with hydrochloric acid, hydrogen sulphide, and ferric chloride, it gives a pale-brown colour; with aniline, potassium dichromate, and acetic acid, a brownish-red colour which on boiling becomes dark-claret; with potassium dichromate and metatolylenediamine hydrochloride, a bluish-green colour which on boiling becomes red; and with bleaching powder, a flocculent precipitate of a *chlorimide* which, on treatment with an alcoholic solution of aniline and hydrochloric acid, gives a deep-red colour.

W. P. W.

$\alpha\beta$ -Benzenylnaphthylenediamine. By A. KÖHL (*Annalen*, 263, 313—315).—Fischer and Hepp (Abstr., 1887, 729, 1114) have shown that $\alpha\beta$ -ethenylnaphthylenediamine is formed when β -ethylnaphthylamine is treated with amyl nitrite and an alcoholic solution of hydrogen chloride; the authors find that, under the same conditions, β -benzylnaphthylamine can be converted into $\alpha\beta$ -benzenylnaphthylenediamine, identical with the compound prepared by Ellb (Annalen, 208, 328) from β -nitrobenzonaphthylamide, and named by him anhydrobenzodiamidonaphthalene. This base separates from alcohol in colourless crystals, and from methyl alcohol in efflorescent prisms containing $\frac{1}{2}$ mol. CH_3O ; it melts at 214° . The hydrochloride, $C_{17}H_{15}N_2 \cdot HCl$, crystallises from hot alcohol in colourless needles.

F. S. K.

Derivatives of Lapachic Acid. By S. C. HOOKER (*Chem. Centr.*, 1891, i, 409; from *Proc. Franklin Inst.*, 1890, 117—124).—Bromolapachone (Abstr., 1889, 999), like lapachone, reacts with alkalis with formation of dihydroxyhydrolapachic acid. By the action of dilute mineral acids, this becomes transformed into hydroxylapachone, which, when redissolved in potash and the solution acidified with acetic acid, again forms the original acid.

Bromolapachone crystallises in two different forms, plates melting at 138.5° , and needles melting at 138° ; of these, the latter appears to be the more stable, for the plates become gradually transformed into the needles. *Dihydroxyhydrolapachic acid*,

melts at 181 — 182° , and also crystallises in two modifications, in prisms and in masses of long, thin needles. The acid forms salts

which are not decomposed by carbonic anhydride. In the absence of mineral acids, dihydroxyhydrolapachic acid is stable.

Hydroxylapachone, $C_{10}H_4O_3$, $\langle \begin{smallmatrix} CH(OH) \\ O \end{smallmatrix} \rangle CHPr$, forms red needles melting at 201.5° . With bromine, it forms no additive compounds, which must have been the case had it possessed the constitution ascribed to it by Paternò.

When treated with bromine in chloroform solution, lapachic acid gives five different compounds. J. W. L.

Boiling Points of some Compounds of High Molecular Weight. By R. SCHWETZER (*Annalen*, 264, 193—196).—The boiling point of anthracene was determined with the aid of Meyer and Goldschmidt's air thermometer (*Ber.*, 15, 141, 303), and found to be 382° as the average of two experiments. The boiling points of various other organic compounds were determined, employing a mercury thermometer filled with nitrogen under pressure, and graduated to about 500° ; the numbers in brackets give the boiling points found in this way. Anthracene (351°), retene (394°), phenylnaphthylcarbazole (454°), β dinaphthylamine (483°), tribenzylamine (380 — 390°), β -dinaphthyl ketone (464°), α -naphthyl phenyl ketone (385°), chrysene (448°), picene (above 500°), dianthryl (above 500°), and tetrahydroxyanthraquinone (above 500°). F. S. K.

Oxidation of Alizarin-green and Alizarindigo-blue. By C. GRAEBE and A. PHILIPS (*Ber.*, 24, 2297—2299).—The authors have obtained a tri-, tetra-, and penta-hydroxyanthraquinoline from alizarin-green and alizarindigo-blue.

Trihydroxyanthraquinoline (hydroxyalizarin-blue) is contained in the portion of alizarin-green which is insoluble in nitrobenzene. It is obtained from this product by sublimation in bluish-violet needles; a good deal is, however, carbonised. It can also be obtained from the sulphonic acid contained in alizarin-green by heating it with hydrochloric acid at 180° .

Tetrahydroxyanthraquinoline is obtained in small quantities by extracting alizarin-green with nitrobenzene, and also from alizarindigo-blue by sublimation.

Pentahydroxyanthraquinoline (trihydroxyalizarin-blue) is the chief constituent of alizarindigo-blue, and may be obtained from it by crystallisation from nitrobenzene and acetic acid, or by heating the crude dye with benzoic chloride, and hydrolysing the ethereal salt thus obtained.

Alizarin-green and alizarindigo-blue, when oxidised with nitric acid (1.35), yield quinolinic acid. Alizarindigo-blue gave 50 per cent. of crude quinolinic acid; pure pentahydroxyanthraquinoline gave 52.5 per cent. Alizarin-blue sulphuric acid, obtained by the action of fuming acid on alizarin-blue, also yields quinolinic acid when oxidised with nitric acid. E. C. R.

Terpenes and Ethereal Oils. By O. WALLACH (*Annalen*, 264, 1—32).—When bromine (2 atoms) is gradually added to a well-

cooled solution of anhydrous pinene (1 mol.) in dry carbon tetrachloride, the halogen is immediately absorbed, but traces of hydrogen bromide are evolved; when a further quantity (2 atoms) of bromine is added, combination takes place more or less quickly, according to the conditions of the experiment, and hydrogen bromide is again evolved; this experiment shows that pinene can combine directly with only 2 atoms of bromine. If, after adding bromine (2 atoms), the carbon tetrachloride is distilled off, a considerable evolution of hydrogen bromide is observed, and there remains a heavy, dark-coloured oil; on boiling this product with alcoholic potash for several hours, and, after evaporating the alcohol, distilling the residue with steam, a complex mixture consisting principally of camphene, pinene hydrobromide, and, perhaps, very small quantities of cymene and pinene dibromide collects in the receiver, and there remains a dark-coloured residue of pinene dibromide. The camphene obtained in this way is, doubtless, produced by the action of the alcoholic potash on pinene hydrobromide, the formation of which is due to the combination of pinene with the hydrogen bromide produced in the original reaction.

Pinene dibromide, $C_{10}H_{16}Br_2$, is easily obtained in a pure condition by dissolving the residue in alcohol, cooling the solution, and recrystallising the precipitated compound from ethyl acetate. The yield is only small, owing to the complicated nature of the original reaction, in which the bromine shows a greater tendency to substitute than to form additive products; in this respect, pinene shows a behaviour intermediate between that of aromatic hydrocarbons and that of other terpenes. Pinene dibromide is very sparingly soluble in cold alcohol, but more readily in warm ethyl acetate and chloroform, from which it separates in colourless, hexagonal crystals melting at $169-170^\circ$; it sublimes readily when heated under reduced pressure, and is optically inactive. As it cannot be obtained either from camphene or from pinene hydrobromide in the manner described above, it must be regarded as formed directly by the combination of bromine with pinene; when heated with aniline at 180° for two hours, it is converted into cymene.

When dextrorotatory limonene tetrabromide (m. p. $104-105^\circ$) is boiled with an alcoholic solution of sodium ethoxide (3 mols.) for 6-7 hours, and the solution then submitted to distillation with steam, a heavy oil collects in the receiver; this product could not be obtained in a pure condition by fractional distillation, but the results of analyses, and a study of its properties, show that it has the composition $C_{10}H_{16}Br$. It boils at $141-145^\circ$ under a pressure of 13-15 mm., has a sp. gr. of 1.217 at 20° , and is dextrorotatory; it combines immediately with bromine (2 atoms), yielding an oily product, and it readily undergoes polymerisation in contact with concentrated sulphuric acid, being converted into an amorphous compound; when treated with a saturated glacial acetic acid solution of hydrogen bromide, it is converted into dipentene tetrabromide (m. p. 123°).

A further investigation of the behaviour of limonene towards bromine has shown that when 4 atoms of the halogen are employed,

hydrogen bromide is invariably evolved, no matter whether the operation is carried out with moist or with anhydrous solvents.

When dextrorotatory limonene tetrabromide is warmed with excess of aniline for five hours, and the solution then boiled over the free flame until the reaction is at an end, a monalkyl derivative of benzene, probably propylbenzene, cymene, and other substances, the nature of which could not be determined, are formed in small quantities.

A *tribromide* of the composition $C_{10}H_{17}Br_3$ is produced when bromine (34 c.c.) is gradually added to a solution of dipentene dihydrobromide (200 grams) in glacial acetic acid (400 c.c.) with constant shaking, any considerable rise of temperature being avoided; as soon as the colour due to free bromine has completely disappeared, alcohol (300 c.c.) is added, and the solution is kept at a low temperature for 24 hours, when the tribromide is partially deposited in crystals; the oily mother liquors are mixed with water, the precipitated oil washed with water, treated with an equal volume of methyl alcohol, and the solution placed in a freezing mixture, when a second crop of crystals is deposited; a further quantity of the crystalline product can be obtained by repeating the process. This tribromide is precipitated from its solution in hot ethyl acetate on the addition of methyl alcohol, in colourless, lustrous plates, which melt at 110° , and decompose at a higher temperature with evolution of hydrogen bromide.

A *hydrocarbon* of the composition $C_{10}H_{14}$, isomeric with cymene, is formed when the tribromide (50 grams) just described is boiled for about 15 minutes with a solution of sodium (12 grams) in alcohol (150 c.c.). It is a colourless liquid boiling at 189° ; its sp. gr. is 0.863 at 20° , and its refraction $n_D = 1.49693$ at the same temperature; it combines with halogen acids, yielding oily compounds. When treated with bromine in well-cooled, alcoholic glacial acetic acid solution until a permanent yellow coloration is produced, it is converted into a *tetrabromide* of the composition $C_{10}H_{14}Br_4$, which is deposited in crystals after keeping for some time. This compound separates from hot ethyl acetate in colourless, asymmetric crystals, $a : b : c = 0.39360 : 1 : 0.35557$, melting at $154-155^\circ$. The mother liquors from the tetrabromide contain small quantities of a compound melting at $103-104^\circ$, which is much more readily soluble in ethyl acetate than the tetrabromide, with which it seems to be isomeric.

Two chlorides, one having the composition $C_{10}H_{17}Cl_3$, and melting at $85-86^\circ$, the other having the composition $C_{10}H_{16}Cl_4$, and melting at 105° , can be obtained by treating dipentene dihydrochloride with chlorine; the preparation and properties of these compounds will be described in a subsequent paper.

F. S. K.

Constitution of Pinene. By G. WAGNER (*Ber.*, 24, 2187-2190).—The author criticises Wallach's explanation (this vol., p. 1078) of the mechanism of the reaction which takes place in the oxidation of oil of turpentine to pinole hydrate (pinene glycol); he considers that the constitution of pinene is probably expressed by the formula

$$\begin{array}{c} \text{CH}_3 - \text{C} = \text{CMe} \\ | \quad \quad | \\ \text{CHPr}^s - \text{CH} - \text{CH}_2 \end{array}$$

which affords a better explanation, not only of the

behaviour of pinene on oxidation, but also of various other reactions, than the formula suggested by Wallach does. F. S. K.

Derivatives of Cantharidin. By F. ANDERLINI (*Ber.*, 24, 1993—2000).—The compound $C_{10}H_{12}NO_3$, obtained from cantharidin by the action of ammonia (Abstr., 1890, 640) is now regarded as *cantharidinimide*, $C_{10}H_{12}O_3.NH$. It is not affected by prolonged boiling with caustic alkalis or baryta, yields a series of alkyl derivatives, and, when heated with acetic anhydride at 230° for about 30 hours, is converted into a crystalline *acetyl* derivative, $C_{10}H_{12}O_3.NAc$, which dissolves readily in alcohol, ether, and benzene, and is hydrolysed by boiling with water or aqueous alcohol.

Cantharidin methylimide, $C_{10}H_{12}O_3.NMe$, is obtained when cantharidin is heated with a slight excess of methylamine in methyl alcohol solution at 140 — 145° for 5—6 hours, and when cantharidinimide is heated with the calculated quantity of sodium carbonate, an excess of methyl iodide, and 10—12 times the amount of methyl alcohol at 100° . It crystallises from water in long, colourless, rhombic needles, $a : b : c = 0.57497 : 1 : 0.74685$, and melts at 125° .

Cantharidin ethylimide, $C_{10}H_{12}O_3.NEt$, prepared either from cantharidin or cantharidinimide, crystallises in colourless, rhombic forms, $a : b : c = 0.52346 : 1 : 0.78677$, melts at 105° , and is readily soluble in the ordinary solvents.

Cantharidin amylimide, $C_{10}H_{12}O_3.NAy$, crystallises with difficulty, melts at 46° , and is soluble in alcohol, ether, and benzene, insoluble in water.

Cantharidin allylimide, $C_{10}H_{12}O_3.NC_3H_5$, crystallises in monoclinic forms, $a : b : c = 0.28226 : 1 : 0.59433$, $\beta = 67^\circ 35'$, melts at 80° , and is soluble in water.

Cantharidin phenylimide, $C_{10}H_{12}O_3.NPh$, crystallises in monoclinic forms, $a : b : c = 2.7798 : 1 : 1.9818$, $\beta = 89^\circ 40'$, melts at 129° , and is readily soluble in alcohol, ether, and benzene, but insoluble in water.

Cantharidin α -naphthylimide, $C_{10}H_{12}O_3.NC_{10}H_7$, crystallises from acetone in lustrous, monoclinic forms, $a : b : c = 0.55814 : 1 : 1.75340$, $\beta = 83^\circ 59'$, and is readily soluble in the ordinary solvents, but insoluble in water.

In addition to the methods already described for that purpose (compare Homolka, Abstr., 1886, 723), cantharic acid can also be prepared by dissolving cantharidin in 5 times the quantity of chlorosulphonic acid, and, after four hours, pouring the solution on to ice, neutralising with barium carbonate, and treating the filtrate with the requisite quantity of dilute sulphuric acid. Cantharic acid crystallises in rhombic forms, $a : b : c = 0.96218 : 1 : 0.68658$, and its oxime (Homolka, *loc. cit.*) in monoclinic forms, $a : b : c = 1.0772 : 1 : 1.2402$, $\beta = 87^\circ 1'$. When heated at 180° for 7—8 hours with a saturated alcoholic solution of ammonia, it is converted into a compound $C_{10}H_{12}NO_3$, which melts at 187° , dissolves readily in the ordinary solvents, and is isomeric with cantharidinimide.

Isocantharidin, $C_{10}H_{12}O_4$, is formed when 1 part of cantharic acid is heated with 4—5 parts of acetic chloride at 135° for three hours. It

crystallises in monoclinic forms, $a : b : c = 1.0273 : 1 : 1.1795$, $\beta = 59^\circ$, melts at $75-76^\circ$, and is readily soluble in alcohol, ether, and benzene, but only sparingly in boiling water.

Isocantharidic acid, $C_{10}H_{14}O_5 + H_2O$, is obtained by boiling the aqueous solution of isocantharidin for three hours until it no longer becomes turbid on cooling. It crystallises in crusts, loses its water of crystallisation at 100° , melts at 153° , and at 163° is converted into an anhydride which melts at $75-76^\circ$, and is reconverted into the acid by boiling with water. It is a bibasic acid. The *silver* salt, with 3 mols. H_2O , and the *barium* salt, with 5 mols. H_2O , are described; the *methyl* salt, $C_{10}H_{12}O_5Me$, melts at $81-82^\circ$, is volatile without decomposition, and dissolves in water and ether. W. P. W.

Gentisin. By S. v. KOSTANECKI (*Chem. Centr.*, 1891, i, 587; from *Schweiz. Wochenschr. Pharm.*, 29, 59-60).—By boiling gentisin with hydriodic acid, methyl is eliminated with formation of *gentisein*, $C_{13}H_8O_5$. It crystallises in fine, straw-coloured needles with 2 mols. H_2O , which again separate at 100° , the colour deepening at the same time. By boiling with anhydrous acetic acid and anhydrous sodium acetate, *triacetylgentisein*, $C_{13}H_5O_5Ac_3$, is formed. It crystallises in large, lustrous needles, sparingly soluble in alcohol, readily soluble in glacial acetic acid. This compound proves the presence of three hydroxyl groups in gentisein, $C_{13}H_5O_5(OH)_3$, and that gentisin is a methyl ether of gentisein, $C_{13}H_5O_5(OMe)(OH)_3$. J. W. L.

Derivatives of Piperidine. By E. LELLMANN and R. JUST (*Ber.*, 24, 2099-2104; see also *Abstr.*, 1887, 604; 1888, 1107; 1890, 1002).—1-*Paratolylpiperidine*, $C_6H_4Me-C_5NH_{10}$, is obtained by heating piperidine with bromotoluene for 10 hours at 270° ; the portion boiling at $260-275^\circ$ is separated from admixed bromotoluene by dissolving in acid, extracting with ether, and reprecipitating the base with alkali. It is a pale-yellow, oily liquid, boils at 262° , and is readily soluble in alcohol, ether, and benzene, and forms a crystalline *platinochloride*, $(C_6H_4Me-C_5NH_{10})_2 \cdot H_2PtCl_6$, which is partially decomposed on warming in aqueous solution.

1-*Parabromophenylpiperidine*, $C_6H_4Br-C_5NH_{10}$, is prepared in a similar manner from paradibromobenzene. It crystallises from ether in brownish plates, and melts at 75° . Its *hydrobromide* forms compact crystals. Hexachlorobenzene is also acted on by piperidine at $250-260^\circ$, three-fifths of the chlorine being converted into hydrochloric acid in 10 hours.

It has been shown in the previous papers that chloro- and bromonitrobenzenes of the ortho- and para-series readily combine with piperidine, whilst the meta-compounds are not acted on. This property may be employed for isolating the latter from a mixture with ortho- and para-compounds, and also for ascertaining whether such a nitro-compound is a meta-derivative or not. Thus, from the mixture obtained by nitrating parabromotoluene, the compound

may be readily isolated by heating with piperidine and warming the

product with concentrated hydrochloric acid, which dissolves out the compound $C_6H_5Me(NO_2) \cdot C_5NH_{10}$ [1 : 3 : 4], and leaves the 1 : 2 : 4-compound as a crystalline cake. Again, the compound obtained by Fittig and Ahrens (*Annalen*, 147, 31) by the action of nitric acid on bromometaxylene does not combine with piperidine, and, therefore, contains the nitro-group in one of the meta-positions to the bromine atoms. If the nitration be carried out with fuming nitric acid, yellow needles of *dinitrobromometaxylene*, $C_6HMe_2Br(NO_2)_2$, are obtained, which melt at 89° , and are also without action on piperidine; hence it has probably the constitution $CH_3 : NO_2 : CH_3 : Br : NO_2 = 1 : 2 : 3 : 4 : 6$.

1-*Orthamidophenylpiperidine*, $NH_2 \cdot C_6H_4 \cdot C_5NH_{10}$, is readily obtained by the reduction of *orthonitrophenylpiperidine* with stannous chloride and hydrochloric acid, and forms small plates which melt at 45.5° , and are soluble in most organic solvents. The *stannochloride*, $C_{11}H_{16}N_2 \cdot H_2SnCl_6$, crystallises in needles and melts at 217° . When the base is warmed with phenylthiocarbimide in alcoholic solution, it yields *piperidyl-1-thiocarbanilide*, $NHPh \cdot CS \cdot NH \cdot C_6H_4 \cdot C_5NH_{10}$, which forms white crystals, and melts at 174° . H. G. C.

Behaviour of Piperidine Bases towards Aromatic Halogen Compounds. By E. LELLMANN and R. JUST (*Ber.*, 24, 2104–2107).

—In continuation of their investigation of the action of halogen compounds on piperidine, the authors have also examined their action on the substituted piperidines. They find that the attraction between these compounds is very much less than with piperidine, and becomes smaller the nearer the alkyl group approaches the nitrogen atom, and the larger its molecular weight is. With the dipiperidyl obtained from nicotine, the reaction, as would be expected in the case of a bi-acid base, takes place rather more readily than with the alkyl derivatives.

Orthoparadinitrophenyl- α -methylpiperidine, $C_6H_3(NO_2)_2 \cdot C_5NH_5Me$, is obtained from *orthoparadinitrochlorobenzene* and *α -methylpiperidine*, and forms a reddish oil, which solidifies after remaining for a long time, but could not be obtained pure. *Orthoparadinitrophenylconiine*, $C_6H_3(NO_2)_2 \cdot C_5NH_5P^{ac}$, forms crystals which melt at 42° , and dissolves in concentrated hydrochloric acid, alcohol, ether, and benzene. *Paranitrophenyldipiperidyl*, $NO_2 \cdot C_6H_4 \cdot C_5NH_5 \cdot C_5NH_{10}$, is obtained as a thick, brown, aromatic-smelling oil, which did not solidify, whilst the *orthoparadinitrophenyldipiperidyl*, $C_6H_3(NO_2)_2 \cdot C_5NH_5 \cdot C_5NH_{10}$, forms a yellowish-red solid, without distinct crystalline form, and melts at 72 – 76° . It is soluble in alcohol, ether, and light petroleum and yields a sparingly soluble crystalline *platinochloride*,

The derivatives obtained from the substituted piperidines do not, therefore, show the power of crystallisation in such a marked manner as the corresponding piperidine compounds, and are, on this account, much more difficult to purify. H. G. C.

Introduction of Bivalent Radicles into Piperidine. By L. RÜGHEIMER (*Ber.*, **24**, 2186—2187).—A compound having the composition $C_{19}H_{19}N$, can be prepared by treating benzoylpiperidine with benzaldehyde and then eliminating the benzoyl group from the condensation product thus obtained; it melts at 89° , has only feeble basic properties, and is probably a dibenzenylpiperidine of the constitution $[(CHPh)_2 = 2 : 6]$. The *hydrochloride*, $C_{19}H_{19}N \cdot HCl$, crystallises from benzene, in which it is sparingly soluble, in large plates and prisms, melts at 164.5 — 166° , and is decomposed by water. The *nitrate*, $C_{19}H_{19}N \cdot HNO_3$, crystallises in colourless plates, and melts at 96.5 — 98° .

A crystalline base can also be obtained from the condensation product of benzoylpiperidine and cuminaldehyde in like manner, but aldehylaldehyde yields an amorphous compound; aldehydes of the fatty series seem to form analogous condensation products.

F. S. K.

Derivatives of Homopiperidic Acid. By W. ASCHAN (*Ber.*, **24**, 2443—2450, *cf.* this vol., p. 466).—*Ethyl γ -phthalimidopropylmethylmalonate*, $C_8H_9O_2N \cdot [CH_2]_3 \cdot CMe(COOEt)_2$, is obtained by heating γ -bromopropylphthalimide (40 grams) for four hours in a reflux apparatus with an alcoholic solution of ethyl sodiomethylmalonate, prepared by mixing ethyl methylmalonate (23 grams) with a solution of sodium (3.7 grams) in 10 times its weight of absolute alcohol. It is an oil which could not be purified either by crystallisation or distillation.

α -Methylhomopiperidic acid, $COOH \cdot CHMe \cdot [CH_2]_3 \cdot NH_2$, prepared by digesting this oil with about 5.5 times its weight of hydrochloric acid (sp. gr. = 1.13) at 170 — 175° for four hours, crystallises in small, flat prisms or scales, melts at 168 — 170° with frothing, or at 157° on heating very slowly, and is readily soluble in water, but insoluble in absolute alcohol and ether. The aqueous solution is neutral to litmus, and has a pure, sweet taste. The salts with bases or acids are extremely soluble, and can be crystallised only with difficulty. The *urochloride* is very soluble and hygroscopic; the *platinochloride*, $(C_8H_{11}O_2N)_2 \cdot H_2PtCl_6$, crystallises in thin, lustrous scales, decomposes at 190° with frothing, and is easily soluble in water, but insoluble in alcohol and ether.

β -Methylpiperidone, $CH_2 \cdot \begin{matrix} CHMe \cdot CO \\ | \\ CH_2 - CH_2 \end{matrix} \cdot NH$, is obtained when α -methylpiperidic acid is heated at 185° , so long as water distils over, and the residue is afterwards distilled at 249 — 250° . It crystallises from light petroleum in small, but well-formed, colourless cubes, melts at 53.5 — 55° , has an odour resembling that of comine, and dissolves readily in all the ordinary solvents with the exception of cold light petroleum.

β -Ethylpiperidone is converted into an oily *nitrosamine* by the action of nitrous acid. The compound is very unstable, decomposing with the evolution of gas even at the ordinary temperature, and when heated at 115 — 117° until gas is no longer given off, yields α -ethyl- δ -valerolactone.

β -Propylpiperidone is gradually reconverted into α -propylhomopiperidic acid by boiling with hydrochloric acid, and on treatment

with nitrous acid gives a yellow oil, having the properties of a nitrosamine.

β -Benzylpiperidone is best prepared by heating α -benzylhomopiperidic acid in quantities of 10–13 grams at 210–215° until water is no longer given off, dissolving the residue in boiling water, and allowing the hot solution to cool slowly. It is slowly reconverted into the acid by boiling with concentrated hydrochloric acid. As already stated (*loc. cit.*), it decomposes at 100°, and the products of the decomposition are now identified as nitrogen and α -benzyl- δ -valerolactone. On reduction with sodium in boiling amyl alcohol solution, β -benzylpiperidone is converted into β -benzylpiperidine, $\text{CH}_2\langle\text{CHBz}\cdot\text{CH}_2\rangle\text{NH}$. This base is an oil of piperidine-like odour, and is characterised by forming a sparingly soluble, crystalline *platinochloride*, $(\text{C}_{11}\text{H}_{17}\text{N})_2\cdot\text{H}_2\text{PtCl}_6$, and an *auerochloride* which melts at 138–140°, and is readily soluble in warm water, alcohol, and ether.

Ethyl β -phthalimidoethylmalonate, $\text{C}_8\text{H}_7\text{O}_2\cdot\text{N}\cdot\text{CH}_2\cdot\text{CH}_2\cdot\text{CH}(\text{COOEt})_2$, is prepared by boiling 10 grams of β -bromomethylphthalimide for four hours in a reflux apparatus with an alcoholic solution of ethyl sodiomalonate obtained from 10 grams of ethyl malonate. It crystallises from light petroleum in colourless scales or flat prisms, melts at 42–44°, is readily soluble in the ordinary solvents, and when digested with five times its weight of hydrochloric acid (sp. gr. = 1.13) at 170–180° for three hours, is converted into γ -amidobutyric acid.

W. P. W.

Substituted Ammonium Compounds. By H. DECKER (*Ber.*, 24, 1984–1987).—In addition to the methiodides described in the previous communication (this vol., p. 736), the author has endeavoured to prepare others, and finds that a number of quinoline derivatives do not combine with methyl iodide under any conditions, thus confirming the work of previous observers. The position of the substituent has a marked influence on this property, and the evidence tends to show that when a radicle is present in the position "1," a methiodide cannot be obtained; thus, 2'-nitroquinoline and 2'-nitro-3-methylquinoline, which form methiodides, no longer do so on the introduction of methyl into this position. The property is seemingly in no way dependent on the relative basicity of the quinoline derivatives, since 2'-nitro-1 : 3-dimethylquinoline forms stable salts, but no methiodide, whilst 2'-nitro-3-bromoquinoline does not give salts under the ordinary conditions, but combines with methyl iodide.

To prepare the methiodides, 3–4 hours heating at 100° with the theoretical quantity of methyl iodide is sufficient for most quinoline derivatives; a higher temperature or an excess of methyl iodide resulting frequently in the formation of insoluble compounds containing iodine. The product is extracted with ether or benzene to remove any unaltered quinoline derivative, and crystallised from water, in which the methiodides are sparingly soluble in the cold. The method can be employed to separate 1-quinoline derivatives from those which form methiodides. The preparation of methiodides is recommended as a means of characterising quinoline derivatives on account of their

stability and characteristic properties, and the readiness with which they can be purified.

W. P. W.

Action of Hypochlorous Acid on Bromoquinolines. By A. WELTER (*J. pr. Chem.* [2], 43, 497—504).—The formation of carbostyryl by the action of hypochlorous acid on quinoline has been investigated by Erlenmeyer and Rosenhek (*Abstr.*, 1886, 244, 559), and by Einhorn and Lauch (*Abstr.*, 1888, 501).

Parabromocarbostyryl [$\text{Br} : \text{OH} = 3 : 2'$] is prepared by gradually adding a solution of 3-bromoquinoline (10 grams) in a little alcohol to a solution of boric acid (150—200 grams) in water ($1\frac{1}{2}$ litres) contained in a reflux apparatus, and, when it has nearly all dissolved, filtering through a hot filter into 9 litres of water; to this is added a solution of bleaching powder (1 part) in cold water (5 parts), and after 24 hours the precipitate is filtered, and dissolved in sodium hydroxide; this solution is cooled, when the *sodium* compound of parabromocarbostyryl crystallises out; it is again dissolved in sodium hydroxide and decomposed by carbonic anhydride, whereby parabromocarbostyryl is precipitated. It crystallises from alcohol in beautiful yellow needles, melts at 269° (uncorr.), and dissolves in alkalis, concentrated acids, chloroform, ether, and alcohol. The *potassium* and *ammonium* compounds and the *platinochloride* were obtained.

3 : 2'-Dibromoquinoline is obtained by heating parabromocarbostyryl with excess of phosphoric bromide for two hours at 100° , decomposing the product with water, neutralising with sodium carbonate, and distilling; it crystallises in white, volatile leaflets, melts at 166 — 167° , and dissolves easily in alcohol and hydrochloric acid. The *platinochloride* was obtained.

Metabromocarbostyryl [$\text{Br} : \text{OH} = 2 : 2'$] is obtained in the same way as parabromocarbostyryl; it crystallises from glacial acetic acid in long, straw-like needles, and from alcohol in microscopical, four-sided tables; it sublimes unchanged in beautiful, long needles, and melts at 288° ; it dissolves also in chloroform and ether. The *platinochloride* and the *sodium* and *potassium* compounds were obtained. The *compound* of it with hypochlorous acid, $\text{C}_8\text{H}_7\text{NBrOCl}$, crystallises in pale-red needles, and melts, when sharply heated, at 194° .

2 : 2'-Dibromoquinoline is obtained by heating metabromocarbostyryl with phosphoric bromide at 130 — 140° , until no more hydrogen bromide is evolved, neutralising with sodium carbonate, distilling with steam, and fractionally crystallising the product from alcohol; it crystallises in colourless needles and hexagonal tables, melts at 134° (uncorr.), and dissolves in alcohol, ether, chloroform, and mineral acids; when heated with aqueous ammonia at 200° , it is converted into metabromocarbostyryl. The *nitro-derivative*, $\text{C}_8\text{H}_4\text{Br}_2\text{NO}_2\text{N}$, crystallises in small, colourless needles, melts at 180° , and dissolves sparingly in hot water and ether, but easily in chloroform and concentrated mineral acids. The corresponding *amido-derivative* was obtained.

Anabromocarbostyryl [$\text{Br} : \text{OH} = 4 : 2'$] is prepared in the same way as parabromocarbostyryl; it crystallises in beautiful needles, melts at

300°, and dissolves sparingly in alcohol. The *potassium* compound is described.

4 : 2'-*Dibromoquinoline*, obtained by heating anabromocarbostyryl with phosphoric bromide, crystallises in small needles, and melts at 86°.

1-Bromoquinoline yields an additive compound with hypochlorous acid (compare Einhorn and Lanch, *Abstr.*, 1888, 502). Decker (this vol., p. 736) has investigated the action of hypochlorous acid on 4'-bromoquinoline.

Fourteen of the 21 isomeric dibromoquinolines are now known.

A. G. B.

Action of Chlorine on Hydroxyquinoline. By T. ZINCKE (*Annalen*, 264, 196–228).—The compounds formed by the action of chlorine on parahydroxyquinoline are analogous in composition and in chemical behaviour to those produced from β -naphthol in like manner (compare Zincke and Kegel, *Abstr.*, 1888, 708; 1889, 265); the two series of compounds are, therefore, in all probability, analogously constituted.

Chlorhydroxyquinoline, $C_9NH_5Cl \cdot OH$ [$OH : Cl = 3 : 4$], is deposited in the form of its hydrochloride when parahydroxyquinoline is treated with chlorine in cold glacial acetic acid solution; if the solution is saturated with chlorine and then kept for some days, tetrachloroketo-tetrahydroquinoline is also formed. The two products can be easily separated by treating the crystalline precipitate with water, in which the keto-derivative is insoluble; the hydrochloride of the hydroxy-compound passes into solution, and is reprecipitated on the addition of hydrochloric acid. Chlorhydroxyquinoline crystallises in long, slender, almost colourless needles, melts at 198°, and sublimes without decomposition; it is soluble in alkaline carbonates. The *hydrochloride*, $C_9NH_5ClO \cdot HCl$, crystallises in yellow plates, and decomposes when heated above 200°. The *platinochloride*, $(C_9NH_5ClO)_2 \cdot H_2PtCl_6 + 2H_2O$, crystallises from hot hydrochloric acid in slender, yellow needles; the *sulphate*, $(C_9NH_5ClO)_2 \cdot H_2SO_4$, is a yellow, crystalline powder, soluble in alcohol. The *acetyl* derivative, $C_9NH_5Cl \cdot OAc$, crystallises from dilute alcohol in long, colourless needles, and melts at 102°.

Dichlorhydroxyquinoline, $C_9NH_4Cl_2 \cdot OH$ [$Cl_2 : OH = 2 : 4 : 3$], is most easily obtained by boiling tetrachloroketotetrahydroquinoline with an aqueous solution of sodium hydrogen sulphite. It crystallises from alcohol in colourless, lustrous needles, melts at 217°, and sublimes at a higher temperature; it is readily soluble in alkaline carbonates, and, when treated with chlorine in glacial acetic acid solution, it is converted into tetrachloroketodihydroquinoline. The *hydrochloride*, $C_9NH_5Cl_2O \cdot HCl + 2H_2O$, is a yellow, crystalline compound, and loses its water at 120–130°. The *platinochloride*,

crystallises in yellow needles, and is very sparingly soluble in water, but more readily in hot dilute hydrochloric acid. The *acetyl* derivative, $C_9NH_4Cl_2 \cdot OAc$, separates from hot alcohol in colourless needles, and melts at 130°.

Trichlorhydroxyquinoline, $C_9NH_3Cl_3O$ [$Cl_3 : OH = 1 : 2 : 4 : 3$], is obtained when tetrachloroketodihydroquinoline is boiled with an aqueous solution of sodium hydrogen sulphite; it crystallises from hot alcohol or benzene in slender, colourless needles, melts at 244° , and is only sparingly soluble in cold alcohol; it forms stable salts with alkalis, and, when treated with chlorine in glacial acetic acid solution, it is converted into tetrachloroketodihydroquinoline. The *hydrochloride*, $C_9NH_4Cl_3O \cdot HCl + H_2O$, crystallises from hot hydrochloric acid in lemon-yellow needles, and is decomposed by warm water; the *platinochloride* forms brownish-yellow needles. The *acetyl* derivative, $C_9NH_3Cl_3 \cdot OAc$, crystallises from hot alcohol in slender, colourless needles, sinters together at 130° , and melts at 139° .

Trichloroketodihydroquinoline, $C_9NH_3 < \begin{matrix} CCl_2 \cdot CO \\ CH : CCl \end{matrix}$, is formed with elimination of 1 mol. HCl when tetrachloroketotetrahydroquinoline is slowly heated to 100° with water; it separates from a mixture of ether and light petroleum in transparent, well-defined, seemingly monoclinic crystals, melts at $105\text{--}106^\circ$, and is readily soluble in hot alcohol, chloroform, and carbon bisulphide; it seems to form a hydrate with water, and it dissolves in alkalis yielding a brownish solution, from which the hydrochloride of dichlorhydroxyquinoline is precipitated on the addition of hydrochloric acid. When heated with an aqueous solution of sodium hydrogen sulphite, and when boiled for a long time with water or dilute acids, it is converted into dichlorhydroxyquinoline. The *hydrochloride*, $C_9NH_4Cl_2O \cdot HCl$, prepared by passing hydrogen chloride into a chloroform solution of the base, crystallises in small needles, and decomposes on exposure to the air.

Anilidodichlorhydroxyquinoline, $C_{15}N_2H_{10}Cl_2O$ [$NHPh : Cl_2 : OH = 1 : 2 : 4 : 3$], is deposited in red needles when aniline is added to a cold alcoholic solution of trichloroketodihydroquinoline; after keeping for 12 hours, the solution is acidified with dilute acetic acid, the insoluble residue dissolved in hot alcohol, reprecipitated from the solution with hydrochloric acid, and the hydrochloride obtained in this way decomposed with sodium acetate. The base exists in two forms, both of which melt at 154° ; when it is dissolved in hot dilute alcohol, and the solution then allowed to cool, long, colourless needles are deposited, but after some time dark-orange, cubic crystals separate from the solution, and finally the colourless needles undergo transformation into the dark crystals; if the latter are again dissolved in alcohol, the same phenomena are observed. Both modifications are readily soluble in alcohol, glacial acetic acid, and benzene, but more sparingly in light petroleum; they dissolve in alkalis yielding an almost colourless solution, in which a heavy, white precipitate is produced on the addition of acetic acid; this precipitate gradually changes to a mass of small, orange crystals. The *hydrochloride*, $C_{15}N_2H_{10}Cl_2O \cdot HCl$, crystallises in brownish, lustrous prisms; the *platinochloride* is decomposed by hot water. The *acetyl* derivative, $C_{15}N_2H_9Cl_2 \cdot OAc$, crystallises from hot alcohol in yellow plates, melts at 170° , and is sparingly soluble in cold alcohol.

Tetrachloroketodihydroquinoline, $C_5NH_3 \begin{smallmatrix} \text{CCl} \cdot \text{CO} \\ \text{CCl} : \text{CCl} \end{smallmatrix}$, can be obtained

by treating dichlorhydroxy- or trichloroketodihydro-quinoline with chlorine in glacial acetic acid solution; the product is purified by recrystallisation from boiling light petroleum, from which it is deposited on cooling in light-yellow, well-defined plates melting at 82–83°. It is readily soluble in ether, chloroform, benzene, glacial acetic acid, hot light petroleum, and hot alcohol, and it dissolves in alkalis yielding a brown solution, which quickly changes, first to green, and then to deep blue; it is gradually converted into trichlorhydroxy-quinoline on prolonged boiling with dilute alcohol or dilute acids. The *hydrochloride*, $C_5NH_3Cl_4O \cdot HCl$, is crystalline, and decomposes on exposure to the air, with liberation of hydrogen chloride.

Anilidotrichloroketodihydroquinoline,

is gradually deposited when excess of aniline is added to a solution of tetrachloroketodihydroquinoline in cold alcohol; it crystallises from glacial acetic acid in brownish-yellow prisms, melts at 200–202° with decomposition, and is only sparingly soluble in alcohol and glacial acetic acid, and insoluble in soda. When treated with stannous chloride in glacial acetic acid solution, it is converted into the anilide of dichlorhydroxyquinoline (see above).

Chloranilidoquinolinequinoneanilide,

is formed when the preceding compound is boiled with aniline in alcoholic solution or treated with aniline at the ordinary temperature; it crystallises from alcohol and glacial acetic acid in dark, ruby-red plates or needles, melts at 180° with decomposition, and is only sparingly soluble in alcohol, but more readily in glacial acetic acid and benzene. The hydrochloride crystallises in brownish, lustrous plates, and is decomposed by water.

Chlorhydroxyquinolinequinoneanilide,

is precipitated when the preceding compound is boiled with 10 per cent. soda and a little alcohol, until it has completely dissolved, and the solution then acidified with acetic acid. It crystallises from hot alcohol in deep-red plates or needles, melts at 195°, and is readily soluble in glacial acetic acid and hot alcohol; it dissolves in soda with a brownish-red coloration, but it is insoluble in sodium carbonate.

Chlorhydroxyquinolinequinone, $C_5NH_3ClO_2$ [$O_2 : Cl : OH = 1 : 4 : 2 : 3$], can be obtained by boiling chloranilido- or chlorhydroxy-quinolinequinoneanilide with alcoholic hydrochloric acid, decomposing the hydrochloride produced in this way with sodium carbonate, and then precipitating the product with acetic acid. It crystallises in dark, reddish-brown needles, melts at about 280° with decomposition, and is readily soluble in sodium carbonate, but only

sparingly in the ordinary organic solvents. The hydrochloride crystallises in yellowish, lustrous plates.

Tetrachloroketotetrahydroquinoline hydrate,

is the final product of the action of chlorine on a glacial acetic acid solution of parahydroxyquinoline. It is a light-yellow, granular, crystalline powder, which turns brown at about 180° , and melts at 200° with decomposition; it is sparingly soluble in the ordinary solvents, cannot be purified by recrystallisation, and when heated with water, it is converted into dichlorohydroxyquinoline.

F. S. K.

Halogen Alkyl Compounds of Parahydroxyquinoline and the Derived Quaternary Ammonium Bases. By A. CLAUS and H. HOWITZ (*J. pr. Chem.*, [2], 43, 505—530).—The authors have already shown (Abstr., 1890, 1323) that the action of alkalis on the halogen alkyl compounds of orthohydroxyquinoline differs from that of the same reagents on parahydroxyquinoline; in the latter case, bases are produced which possess all the characteristic properties of quaternary ammonium bases. It is also found that alkalis and moist silver oxide produce the same bases when they act respectively on parahydroxyquinoline, but different bases when they act on paraalkoxyquinoline. The first portion of this paper is devoted to the authors' explanation of these phenomena, involving some remarks on the constitution of quinoline and isoquinoline; for the appreciation of these the original must be consulted.

Parahydroxyquinoline methochloride [$\text{OH}:\text{MeCl} = 3:1$] (*loc. cit.*) loses 1 mol. H_2O at 100° , becoming porcelain-like, but retaining its crystalline form; it darkens at 250° , and at 270 — 275° it froths up and decomposes. The *platinochloride* decomposes at 255° .

Parahydroxyquinoline methosulphate, $(\text{C}_8\text{NH}_3\cdot\text{OH})_2\text{Me}_2\text{SO}_4$, obtained by double decomposition from the methiodide and silver sulphate, crystallises from aqueous alcohol in slender, yellowish needles, with 5 mols. H_2O , which are lost at 110° .

Parahydroxyquinoline methohydroxide, $\text{C}_8\text{NH}_3\cdot\text{OH}\cdot\text{MeOH}$, is obtained by the action of alkalis, ammonia, or moist silver oxide on the methyl halogen compounds, or by decomposing the methosulphate with barium hydroxide. It is very soluble in water, yielding a yellow solution, from which it crystallises only after prolonged exposure over sulphuric acid, when it forms bright-yellow, flat needles (with 1 mol. H_2O); it dissolves freely in hot alcohol to a reddish solution, from which it crystallises on cooling in beautiful, yellow prisms (with 1 mol. H_2O); both solutions are strongly alkaline. It is quite insoluble in ether, which precipitates it in yellow needles from alcohol; hot chloroform dissolves it slightly with a violet colour. It loses its water of crystallisation at 100 — 110° , becoming nearly black, but it does not fully decompose until 200° . Hydrochloric acid converts it into the methochloride. When it is exposed over sulphuric acid for 14 days, it loses 2 mols. H_2O , becoming *parahydroxyquinolinemethyl-*

betaine, C_9NH_8MeO ; this retains the crystalline form of the methohydroxide, but is dark red and opaque; it is very hygroscopic, recombining with water to form the methohydroxide. The methohydroxide absorbs carbonic anhydride both in aqueous and alcoholic solution very readily, the solution becoming brighter in colour and less alkaline, but the carbonate which is probably formed could not be isolated; the addition of ether to the solution precipitates only the methohydroxide.

Parahydroxyquinoline ethobromide, $C_9NH_8 \cdot OH, EtBr$, is easily obtained by heating the components for several hours in a closed vessel on the water-bath; it crystallises in large, brilliant, vitreous, anhydrous tables and columns, decomposes at $240-245^\circ$, and dissolves easily in alcohol and water.

Parahydroxyquinoline ethohydroxide crystallises in amber-red, vitreous prisms and columns (with 1 mol. H_2O); it is very similar in properties to the methohydroxide, but is somewhat more soluble in hot chloroform and less stable, decomposing at 140° .

Parahydroxyquinoline benzylchloride, $C_9NH_8 \cdot OH, C_6H_5Cl$, obtained by heating a mixture of benzyl chloride with parahydroxyquinoline in molecular proportion on the water-bath, crystallises in massive, colourless tables (with $1\frac{1}{2}$ mols. H_2O); if a hot concentrated solution of it is rapidly cooled, it separates as a yellowish oil which crystallises with difficulty; it loses its water of crystallisation at 100° and melts with decomposition at $235-237^\circ$. The *platinochloride* is described. The *benzyhydroxide*, prepared like the methohydroxide, crystallises from a hot aqueous solution in brilliant, red, long columns or short prisms (with 2 mols. H_2O) of the colour of potassium dichromate; it is sparingly soluble in cold water, but easily soluble in hot water and alcohol to reddish-yellow, strongly alkaline solutions; it is insoluble in ether, but sparingly soluble in chloroform, which, however, will not extract it from its aqueous solution; it melts in its water of crystallisation at 100° , and decomposes at $120-125^\circ$. When the crystallised benzyhydroxide is exposed over sulphuric acid for some 13 days, it loses 3 mols. H_2O , being converted into the *anhydride*, $C_9NH_8 \cdot O \cdot CH_2Ph$, which is a dark-red, very hygroscopic powder; water reconverts it into the hydroxide.

A. G. B.

Homologues of Tetrahydroquinoline. By E. BAMBERGER and P. WULZ (*Ber.*, 24, 2055—2076).—*Tetrahydro-1-methylquinoline*, C_9H_8Me $\begin{matrix} CH_2 \cdot CH_2 \\ | \\ NH \cdot CH_2 \end{matrix}$, is obtained by reducing 1-methylquinoline with granulated tin and hydrochloric acid, decomposing the stannochloride with aqueous soda, distilling in a current of steam, and extracting the distillate with ether. It is a colourless oil which has a penetrating odour, boils at $255-257^\circ$ under 717 mm. pressure, and quickly assumes a yellow colour in the air. Its *hydrochloride*, $C_{10}H_{13}N, HCl$, forms monosymmetric tablets, and is readily soluble in water, hot chloroform, and alcohol, but insoluble in benzene, ether, and light petroleum. Its acid solution becomes brownish-yellow on the addition of potassium dichromate, and afterwards assumes a dark, brownish-green colour. The *acetyl* compound, $C_{10}H_{13}N, Ac$, forms vitreous prisms,

melts at 53—54°, and boils at 297—299° under a pressure of 718 mm., and the *nitroso*-compound, $C_{10}H_{12}N \cdot NO$, which separates from dry ethereal solution in thin, almost colourless, six-sided plates, and from alcohol in monosymmetric crystals, is readily soluble in organic solvents, and melts at 51°.

Tetrahydro-1-methylquinoline also combines with diazobenzene chloride if all mineral acids be removed by the addition of sodium acetate, forming the *diazoamido*-compound, $C_{10}H_{12}N \cdot N_2Ph$, which crystallises in slender, yellow needles, and shows all the characteristic reactions of benzene diazoamido-compounds. It is at once converted in alcoholic solution by a trace of mineral acid into the isomeric azo-colouring matter.

Tetrahydro-1-methylquinoline-3-azobenzenesulphonic acid,

is obtained by the action of paradiazobenzenesulphonic acid on the hydrochloride of the base suspended in water. The liquid, as in the case of tetrahydroquinoline, at once assumes a red colour, and in a short time deposits small, brownish-violet needles. It is sparingly soluble in boiling water, readily in alkalis, and is precipitated from the latter solutions, on the addition of hydrochloric acid, in feathery aggregates of dark-violet needles. It colours wool and silk orange-yellow in an acid-bath, and shows the bad tinctorial properties of the tropæolines in a marked degree. Its *sodium* salt forms brick-red flakes, which gradually change to thin, lustrous plates with a green surface lustre.

The azo-colour is converted into the corresponding *tetrahydro-1-methyl-3 amidoquinoline*, $C_9NH_8Me \cdot NH_2$, by treatment with tin and hydrochloric acid; the stannochloride first formed is decomposed by aqueous soda, the base extracted with ether, and converted into the *hydrochloride*, which is purified by dissolving in alcohol and a little water, adding ether till turbidity commences, and allowing to crystallise; it then forms monosymmetric tablets ($a : b : c = 2.3876 : 1 : 0.8830$, $\beta = 77^\circ 46.9'$). It does not melt at 310°. The base shows all the properties of a paradiamidobenzene, giving the various colouring matters, such as thionins, indamins, safranins, &c., characteristic for this class of compounds.

Tetrahydro-3-methylquinoline, $C_9NH_{10}Me$, is obtained from 3-methylquinoline in the manner already described. It forms silver-white prisms, melts at 38°, boils at 262.3° under a pressure of 712 mm., and is readily soluble in organic solvents, very slightly in water. The *hydrochloride*, $C_{10}NH_{13} \cdot HCl$, crystallises in large, silky needles or vitreous prisms, melts at 189°, and is readily soluble in alcohol and water, insoluble in ether, light petroleum, and benzene. Its neutral solution gives a reddish-brown coloration with ferric chloride, which finally becomes olive-green. The *acetyl* compound, $C_{10}NH_{13} \cdot Ac$, is a thick, colourless oil and boils at 302—305° under a pressure of 719 mm.; the *nitroso*-compound, $C_{10}NH_{13} \cdot NO$, forms long, straw-yellow, flat prisms, belonging to the monosymmetric system, melts at 65°, and gives Liebermann's reaction. The *diazoamido*-compound, $C_{10}NH_{13} \cdot N_2Ph$, crystallises in beautiful, satiny prisms, melts at 74.5°.

and does not yield the isomeric compound even on boiling with acids, but is simply converted into phenol and tetrahydro-3-methylquinoline, according to the characteristic reaction for diazoamido-compounds, in which the hydrogen atom in the para-position is displaced, as, for example, in methylparatoluidine (this vol., p. 1202). In other respects this compound shows the reactions of a diazoamido-compound.

Tetrahydro-3-methylquinoline-1-azobenzenesulphonic acid,

is formed by the action of paradiazobenzenesulphonic acid on tetrahydro-3-methylquinoline, but the reaction takes place much less readily and with a smaller yield than in the case of the 1-methyl compound, which is characteristic of compounds in which the para-position to the amido-group is occupied. The colouring matter is a dark-violet, crystalline powder, and dissolves in alcohol and to a smaller extent in water, forming a wine-red solution, which changes to violet on the addition of mineral acids. Its *sodium* salt forms claret-coloured needles, with a brownish-green metallic lustre. The colouring matter dyes wool and silk red in an acid-bath.

1-*Amidotetrahydro-3-methylquinoline*, $C_6NH_5Me \cdot NH_2$, is formed by the reduction of the azo-colour with zinc-dust and soda solution. Its *hydrochloride* forms colourless prisms with a vitreous lustre and melts at 216° . Its neutral solution gives, with oxidising agents, the bordeaux-red coloration so characteristic of orthodiamido-compounds, and it also behaves towards hydroxynaphthoquinone like other alkylated orthodiamidobenzenes, forming a rosindone (this vol., p. 746). It further resembles these compounds inasmuch as it is acted on by acetic acid with formation of an anhydro-base or *imid-*

azole, $C_6H_4Me \cdot \begin{smallmatrix} N \\ \diagup \diagdown \end{smallmatrix} CMe$, which crystallises from light petroleum in long, white needles or small, flat, lustrous prisms, melts at 163° , distils unchanged at about 360° , and sublimes in beautiful needles. Its *piorate* forms a sandy, yellow, crystalline powder, and the *chromate* fascicular aggregates of yellow needles. When heated with phthalic anhydride, it yields the *phthalone*, $C_{12}H_{11}N_2 \cdot CH : C_2O_2 \cdot C_6H_4$, which crystallises from acetic acid in slender, golden-yellow prisms with a silky lustre, and does not melt at 310° .

Sulphobenzenediazoamidotetrahydro-3-methylquinoline,

is always formed together with the azo-colour above described, in spite of the presence of a large excess of mineral acid, which again forms a striking example of the similarity between the hydroquinoline and methylparatoluidine (this vol., p. 1202). The compound is isolated as the *sodium* salt, which has a pure white colour, and explodes on heating; the *barium* salt forms white, glistening plates.

Tetrahydro-1 : 3-dimethylquinoline, $C_8NH_5Me_2$, is obtained by the reduction of 1 : 3-dimethylquinoline in the usual manner, and is a colourless oil boiling at $272-273^\circ$ under a pressure of 720 mm. The *hydrochloride*, $C_{11}NH_{12} \cdot HCl$, crystallises in rhombic prisms ($a : b : c$

= 0.6694 : 1 : 1.0880), and melts at 212° ; in neutral solution it gives with ferric chloride a yellowish-green coloration, which gradually changes to emerald-green, and, on warming, becomes yellowish-brown. The *acetyl* compound is a thick, colourless oil boiling at 313.5° under a pressure of 719 mm., and the *nitroso*-compound, $C_{11}NH_{14}NO$, crystallises from alcohol on addition of water in thin, lustrous, polygonal plates, melts at 42° , and gives Liebermann's reaction. The *diasoamido*-compound, $C_{11}NH_{14}N_2Ph$, forms thin, strongly lustrous prisms, melts at $88-89^{\circ}$, and undergoes no molecular change with mineral acids, but is simply converted into phenol and tetrahydro-1 : 3-dimethylquinoline.

The above results show that tetrahydro-1-methylquinoline, tetrahydro-3-methylquinoline, and tetrahydro-1 : 3-dimethylquinoline correspond exactly in their properties with methylorthotoluidide, methylparatoluidine, and asymmetrical methylxylydine respectively, and form, therefore, additional evidence in favour of Bamberger's theory that the tetrahydroquinolines have no longer any specific quinoline properties, but behave simply as substituted amidobenzenes (Abstr., 1890, 1301).

H. G. C.

Tetrahydro-1-amidoquinaldine. By E. BAMBERGER and P. WULZ (*Ber.*, 24, 2049-2055).—According to Bamberger's theory (Abstr., 1890, 1301) the tetrahydro-derivatives of 1-amidoquinolines should behave in all respects as alkyl-substituted orthodiamidobenzenes. To test the truth of this supposition, the authors have prepared tetrahydro-orthamidoquinaldine and examined its properties, which they find to agree exactly with the demands of the theory.

Tetrahydro-1-amidoquinaldine, $NH_2 \cdot C_6H_3 < \begin{smallmatrix} CH_2 \cdot CH_2 \\ NH \cdot CHMe \end{smallmatrix}$, is readily formed by boiling orthamidoquinaldine with tin and hydrochloric acid, collecting the stannochloride, triturating it with aqueous soda until it forms an emulsion, and extracting the latter with chloroform. It gives the red coloration characteristic of orthodiamido-compounds with ferric chloride and potassium dichromate, and, on boiling with acetic acid, acetic anhydride, and sodium acetate, yields an anhydro-base, or imidazole, according to Hantzsch's nomenclature, which has

the constitution $\begin{smallmatrix} CH_2 < CH_2 \cdot CHMe \\ CH < C \\ & \parallel \\ & C = CH \end{smallmatrix} > \begin{smallmatrix} N \cdot CMe \\ C \\ C \cdot N \end{smallmatrix}$, and is termed by the

authors " *α -methyltetrahydroperichinaldimidazole*." When crystallised slowly from ether, it forms acute, flat prisms, having an adamantine lustre, and melts at 110° ; it possesses all the usual characteristics of an imidazole, is an extremely stable base, readily soluble in acids, and does not give the least coloration with oxidising agents. Its *platinichloride* forms lustrous, orange-red prisms, and may be crystallised without decomposition from boiling water.

In the methylated imidazoles of the benzene series, the methyl group, like that in quinaldine, readily undergoes condensation. For example, Bamberger and Berlé will shortly publish a paper showing that the imidazole 1 : 3 : 4-diamidotoluene, $C_6H_3Me < \begin{smallmatrix} NH \\ N \end{smallmatrix} > C \cdot CH_3$,

readily combines with phthalic anhydride, forming the *phthalone*, $C_6H_5Me \leftarrow \begin{smallmatrix} NH \\ N \end{smallmatrix} \rightarrow C \cdot CH : C_2O_2 \cdot C_6H_4$. The above imidazole in like manner combines with phthalic anhydride, forming a phthalone of the formula $C_6H_5Me \leftarrow \begin{smallmatrix} N \\ N \end{smallmatrix} \rightarrow C \cdot CH : C_2O_2 \cdot C_6H_4$, which separates from acetic acid on the addition of water in indistinct, yellow crystals, and sublimes in slender, lustrous needles. That the condensation has not taken place between the methyl group of the reduced pyridine ring is shown by the fact that α -tetrahydroquinoline itself does not form a phthalone with phthalic anhydride.

The paper also contains a reply to certain criticisms of Hinsberg (this vol., p. 393) with regard to the centric formula proposed by Bamberger for piaseleins.

H. G. C.

Derivatives of 1-Methylquinoline and 3-Methylquinoline.

By E. LELLMANN and H. ZIEMSEN (*Ber.*, 24, 2116—2120).—3-Nitro-1-methylquinoline, $C_9NH_7Me \cdot NO_2$, is prepared by means of Skraup's reaction from nitro-orthotoluidine, and forms delicate crystalline nodules, melts at 129° , and is scarcely soluble in water, but readily in alcohol. The *hydrochloride*, $C_{10}H_8N_2O_2 \cdot HCl + H_2O$, crystallises in white nodules, and the *platinochloride*, $(C_{10}H_8N_2O_2)_2 \cdot H_2PtCl_6$, in beautiful rhombic crystals. 1-Methylquinolinesulphonic acid, $C_9NH_7Me \cdot SO_3H$, is obtained by the action of fuming sulphuric acid, containing 1 part of anhydride in 3 parts of acid, on 1-methylquinoline, and is isolated by means of its barium salt; it crystallises from water in concentric aggregates of slender needles, is sparingly soluble in cold, more readily in hot water, but insoluble in alcohol; and on heating blackens without melting. The *nickel* salt,

forms green, six-sided plates. When treated with tin and hydrochloric acid on the water-bath, it yields *tetrahydro-1-methylquinolinesulphonic acid*, $C_9NH_7Me \cdot SO_3H$, which crystallises in colourless plates.

3-Methylquinolinesulphonic acid, $C_9NH_7Me \cdot SO_3H$, is obtained in the same manner as the 1-methyl compound, and forms yellowish crystals, does not melt or decompose at 280° , and is very slightly soluble in water, and insoluble in alcohol. The *zinc* salt, $(C_{10}NH_8SO_3)_2Zn + 4H_2O$, forms white, crystalline nodules, and the *silver* salt a white, voluminous precipitate. On reduction, it yields *tetrahydro-3-methylquinolinesulphonic acid*, $C_9NH_7Me \cdot SO_3H + 2H_2O$, which crystallises from water in silky needles.

The 1-methylquinoline-3-sulphonic acid obtained by Herzfeld (*Abstr.*, 1884, 1199) from orthotoluidinesulphonic acid requires nearly 500 parts of water at 18.8° for its solution, and forms a *barium* salt $(C_{10}NH_8SO_3)_2Ba + 5H_2O$, crystallising in white, asbestos-like aggregates of needles. On reduction, it is converted into *tetrahydro-1-methylquinoline-3-sulphonic acid*, $C_9NH_7Me \cdot SO_3H$, which forms colourless crystals, and, in aqueous solution, gives, with potassium dichromate, a brown, and with ferric chloride, a green coloration.

H. G. C.

Constitution of Phenanthroline Bases. By H. SCHIFF (*Ber.*, 24, 2127—2130).—This paper is a reply to the criticisms of v. Miller (this vol., p. 1103) on the constitutional formulæ put forward by the author and Vanni (*Abstr.*, 1890, 138) for the phenanthroline derivatives; the author accepts the formulæ assigned by Miller to the compounds in question, but thinks that Miller has gone a little too far in stigmatising the whole of his (the author's) experimental work as incorrect. F. S. K.

Reduction of Tricyclic Systems. By E. BAMBERGER (*Ber.*, 24, 2463—2469).—As the two best known tricyclic compounds, anthracene and phenanthrene, take up only 2 and 4 atoms of hydrogen respectively on reduction, attention has been directed to the effect of reduction on the naphthaquinolines, and the results obtained with α -naphthaquinoline are given in the two following abstracts. The reduction of bicyclic compounds is, in all respects, comparable with that of tricyclic compounds (see *Abstr.*, 1890, 1299), and proceeds in two well-defined stages, a tetrahydro-derivative being formed with tin and hydrochloric acid, and an octohydro-derivative with sodium and amyl alcohol as reducing agents. In every case, 4 hydrogen atoms are taken up in the first instance by the "pyridine ring" and the resulting tetrahydro-naphthaquinolines resemble the alkylated naphthylamines in properties. The further addition of 4 hydrogen atoms leads to the reduction of one or other of the two nitrogen-free rings with the production of octohydro-derivatives, having the properties of "alicyclic" or "aromatic" alkylated tetrahydro-naphthylamines as the case may be. α -Naphthaquinoline gives only the "aromatic" octohydro-derivative on reduction. The remainder of the paper is devoted to a restatement of the effect of reduction on the properties of the naphthaquinolines, for which a previous paper (*Abstr.*, 1890, 1303) may be consulted.

W. P. W.

Tetrahydro- α -naphthaquinoline. By E. BAMBERGER and L. STETTENHEIMER (*Ber.*, 24, 2472—2480).— α -Naphthaquinoline is best prepared by heating α -naphthylamine (100 grams), nitrobenzene (46 grams), glycerol (178 grams), and concentrated sulphuric acid (141 grams) for five hours, or longer, at 160°, stirring the product into four times its volume of water, adding a concentrated solution of caustic potash (65—70 grams), filtering from the separated resin and potassium sulphate, rendering strongly alkaline with aqueous caustic soda, and extracting with ether. After removal of the ether by evaporation, the oily residue is dissolved in sulphuric acid (55 grams) diluted with about 13 times its weight of water, and purified by adding concentrated aqueous potassium dichromate to the boiling solution until no further separation occurs and the solution becomes green, filtering, rendering alkaline with caustic soda, and extracting with ether. It crystallises from light petroleum in colourless, thick, monoclinic tables, melts at 52°, boils at 223° under 47 mm., at 338° under 719 mm. pressure (not at 251° under 747 mm. pressure, as stated by Skraup), and has only a very slight odour unlike that of quinoline. On treatment in concentrated hydrochloric solution with

ferric chloride, it yields a compound which crystallises from alcohol in golden-yellow, silky needles, and dissolves readily in water, but only sparingly in hydrochloric acid.

Tetrahydro- α -naphthaquinoline, $C_{13}H_{13}NH$, is obtained when α -naphthaquinoline (20 grams), dissolved in hydrochloric acid, is gradually added to a boiling mixture of tin (80 grams) and 38 per cent. hydrochloric acid (500 grams), and heated until the metal is dissolved. The yield amounts to 13–14 grams of the tetrahydro-derivative with the quantities given, and, in addition, a base of high melting point is formed, which can readily be separated from the chief product, as it dissolves only sparingly in ether and light petroleum. Tetrahydro- α -naphthaquinoline crystallises from light petroleum in snow-white, strongly-lustrous scales, melts at 46° and dissolves readily in the ordinary solvents. The solutions exhibit a marked blue fluorescence, which disappears, however, on the addition of a trace of an alkali or mineral acid. Oxidising agents, added to the acid solution, produce an intense carmine colour, and when the solution to which potassium dichromate has been added is allowed to remain for a few minutes, the chromate of a new base separates in dark-green needles, resembling quinhydrone in appearance. The *acetyl* derivative is a viscid oil. The *hydrochloride*, $C_{13}H_{13}NH \cdot HCl$, crystallises in thick prisms, melts at 260 – 261° , is tolerably soluble in water, sparingly soluble in hydrochloric acid, and, when evaporated with hydrochloric acid, is converted into a new (? polymeric) base which crystallises in lustrous needles, does not melt at 270° , and is very sparingly soluble in ether and light petroleum (*v. supra*). The *nitroso*-derivative, $C_{13}H_{13}NH \cdot NO$, crystallises from light petroleum in flat, broad, lemon-yellow prisms, melts at 59.5° , and is very soluble in the ordinary solvents, water excepted.

Phenylazotetrahydro- α -naphthaquinoline crystallises from dilute alcohol in groups of cherry-red needles which exhibit a strong bronze lustre, dissolve in the ordinary solvents with a deep orange-red colour, and in concentrated sulphuric acid with a cornflower-blue colour. The *sulphate*, $(C_{11}H_{11}N \cdot N \cdot Ph)_2 \cdot H_2SO_4$, crystallises in olive-green, flat prisms, and yields violet-red solutions. *Sulphophenylazotetrahydro- α -naphthaquinoline*, $C_{11}H_{11}NH \cdot N \cdot C_6H_4 \cdot SO_3H$, is a dark violet-red, crystalline powder, and its *sodium* salt an orange-red, crystalline precipitate.

Paramidotetrahydro- α -naphthaquinoline, obtained by reduction of the phenylazo-derivative with stannous chloride and hydrochloric acid, dissolves readily in alcohol and ether, and is very unstable. The *hydrochloride*, $C_{13}H_{13}N_2 \cdot 2HCl$, crystallises in small, white needles, does not melt at 300° , and dissolves readily in water and dilute alcohol, but very sparingly in strong hydrochloric acid. On treatment with hydrochloric acid, hydrogen sulphide, and ferric chloride, it gives a brownish-red coloration; with aniline, potassium dichromate, and acetic acid, a brownish-red colour which on boiling becomes dark-claret, with α -naphthol in alkaline solution a greenish-blue, flocculent precipitate, and with bleaching powder a chlorimide which dissolves readily in alcohol and ether. When the hydrochloride is fused with a mixture of aniline hydrochloride with some aniline and amidoazobenzene for

some minutes, a deep violet-red melt is obtained, which, in alcoholic solution, has a beautiful violet colour, and exhibits an intense reddish-violet fluorescence. The production, under these conditions, of colouring matters which form fluorescent alcoholic solutions serves to distinguish paradiamines of the naphthalene series from those of the benzene series.

W. P. W.

"Aromatic" Octohydro- α -naphthaquinoline. By E. BAMBERGER and L. STEITENHEIMER (*Ber.*, 24, 2481—2495).—*ar.-Octohydro- α -naphthaquinoline*.^{*} $C_{13}H_{16}.NH$, is prepared by reducing α -naphthaquinoline dissolved in 20 times its weight of amyl alcohol with 2.5 times its weight of sodium, shaking the product with an equal volume of water, treating the upper layer with hydrochloric acid, removing the amyl alcohol by steam distillation, extracting the residue with ether to remove impurities, adding caustic soda to alkaline reaction, and purifying the liberated base by steam distillation or extraction with ether. The yield amounts to at least 60 per cent. of the α -naphthaquinoline reduced. It crystallises in thick, colourless rhombohedra, melts at 47—48°, boils at 216° under 37.5 mm. pressure, is only slightly volatile with steam, has a peculiar, sweet odour, and dissolves readily in all ordinary solvents, except water. Like the "aromatic" tetrahydronaphthylamines, it reduces silver nitrate in alcoholic solution; with ferric chloride in acid solution, it gives, on warming, a beautiful carmine colour, which disappears on cooling, with potassium dichromate, a carmine colour, either on warming or after remaining for a short time in the cold, and with chromic acid, a floating, deep violet-red colour. The *hydrochloride*, $C_{13}NH_{17}.HCl$, crystallises in monoclinic tables, $a : b : c = 1.0789 : 1 : 1.7101$, $\beta = 68^\circ 7'$; forms observed ∞P_{∞} , ∞P , $\frac{1}{2}P_{\infty}$, and P_{∞} , and dissolves very readily in water, but only sparingly in hydrochloric acid; the *hydrogen sulphate* $C_{13}NH_{17}.H_2SO_4$, crystallises from ether-alcohol in stellate groups of needles, melts at 187°, and is extremely soluble in water; the *picrate*, $C_{13}NH_{17}.C_6H_2(NO_2)_3.OH$, melts at 155—156°, and is tolerably soluble in hot water; the *platinochloride*, $(C_{13}NH_{17})_2.H_2PtCl_6$, is a crystalline powder, which, by varying the conditions of preparation, seems to exist in three forms of different colours and degrees of hydration.

The *nitroso-derivative*, $C_{13}NH_{16}.NO$, crystallises from alcohol in small, yellowish rosettes, and melts at 77.5°. The *acetyl derivative*, $C_{13}H_{16}.NAC$, crystallises from light petroleum in colourless, lustrous, triclinic prisms, melts at 68—69°, and dissolves sparingly in water but readily in the ordinary solvents. The *methyl derivative*, $C_{13}H_{16}.NMe$, crystallises from alcohol in large, thin, nacreous scales, and melts at 37—38°; its *hydriodide*, $C_{13}H_{16}.NMe.HI$, crystallises from hot water in long, lustrous, silky needles, and melts at 202°, and its *platinochloride* is a yellow, crystalline precipitate.

Sulphophenylazo-ar.-octohydro- α -naphthaquinoline,

crystallises in slender, violet-brown, lustrous needles, is sparingly .

* For nomenclature, compare Abstr., 1890, 1303.

soluble in alcohol and water, dissolves in concentrated sulphuric acid with a deep-violet colour, and, in an acid-bath, dyes wool and silk a bright red. *Phenylazo-ar.-octohydro- α -naphthaquinoline* is obtained as sulphate when the reddish-yellow (p diazoamido-) compound resulting from the action of diazobenzene chloride on octohydro- α -naphthaquinoline in the presence of excess of sodium acetate is warmed with dilute sulphuric acid. It crystallises in lustrous, orange-red prisms, melts at 118.5° , and is very sparingly soluble in alcohol. Its *sulphate* crystallises from alcohol in beautiful cherry-red prisms with a bronze lustre, melts at 190.5° and dissolves in concentrated sulphuric acid with an olive-green colour.

ar.-Octohydroparamido- α -naphthaquinoline, $\text{NH}_2 \cdot \text{C}_{15}\text{H}_{15} \cdot \text{NH}$, obtained by the reduction of phenylazo-*ar.-octohydro- α -naphthaquinoline* with stannous chloride in hydrochloric acid solution, forms tufts of lustrous, flat, white prisms, melts at 97° , is not affected by exposure to light and air, and dissolves very readily in chloroform and alcohol, easily in ether, but only sparingly in water or cold light petroleum. The *hydrochloride* is very soluble in water, and crystallises in lustrous, white needles. With hydrochloric acid, hydrogen sulphide, and ferric chloride, the aqueous solution of the salt gives a thionine of a beautiful crimson colour; with metatolylonediamine hydrochloride and sodium acetate, it yields colouring matters of the tolylene-blue and tolylene-red series; with α -naphthol in alkaline solution, it forms a beautiful greenish-blue dye of the indophenol class; with aniline hydrochloride and potassium dichromate, it gives colouring matters of the indamine and saffranine series; and when the base is heated with amidoazobenzene, aniline hydrochloride, and a little aniline, it yields a melt which dissolves in alcohol, forming a dichroic, non-fluorescent solution which appears violet by reflected light, and by transmitted light, red.

Octohydro- α -naphthaquinoline is distinguished by the readiness with which it parts with the hydrogen added on to the "pyridine" nucleus, and undergoes condensation when oxidised. *Di-tetrahydro- α -naphthaquinoline*, $\text{C}_{18}\text{H}_{22}\text{N}_2$, is obtained in this way when the octohydro-compound, dissolved in dilute sulphuric acid, is oxidised with potassium dichromate; the intense red colour at first produced disappears slowly, and a voluminous, yellow precipitate of the chromate of the new base separates; this is decomposed by caustic soda, and the base purified by crystallisation from a mixture of chloroform and alcohol. It forms lustrous, white needles, melts at 282° , and is very soluble in benzene and chloroform, much less so in alcohol, and almost insoluble in light petroleum. It does not form an acetyl derivative, is a tertiary base, gives no reaction in chloroform solution with bromine, and does not yield colouring matters with diazotised bases.

W. P. W.

Methanetriquinol or Triquinylmethane. By O. RHOUSSOPOULOS (*Ber.*, 24, 2267—2268).—The author draws attention to the fact that he has already described salts of the compound $\text{CH}(\text{C}_6\text{NH}_4)_3$, (*Abstr.*, 1883, 600), which has been prepared by Noelting and

Schwartz, and named by them triquinylmethane (this vol., p. 1106). The author obtained his salts by the action of quinoline on iodoform and chloroform, and named them methanetriquinol hydriodide and methanetriquinol hydrochloride, the residue of the quinoline being called quinolil.
E. C. R.

Strychnine. By J. TAFEL (*Annalen*, 264, 33—84).—Further investigation has shown that the compound named "strychnol" by Loebisch and Schoop (*Abstr.*, 1886, 814), and previously described by the author as strychnine monhydroxide (*Abstr.*, 1890, 1447), is not a phenol, but an imido-acid of the composition

so that it may be suitably named *strychnic acid*. The substance, of the composition $\text{C}_{21}\text{H}_{23}\text{N}_2\text{O}_4$, obtained by Gal and Etard (*Bull. Soc. Chim.*, 31, 98) by heating strychnine with a solution of barium hydroxide at 130° , and named by them dihydrostrychnine, loses 1 mol. H_2O at 135° , and has, therefore, the composition $\text{C}_{21}\text{H}_{24}\text{N}_2\text{O}_3 + \text{H}_2\text{O}$; as it is isomeric with strychnic acid, and, also, gives almost all the reactions of the latter, it may be termed *isostrychnic acid*. Both these acids are formed when strychnine is treated with alcoholic soda at 100° or with barium hydroxide at 140° , but the relative quantity of the two compounds depends, to a very considerable extent, on the temperature at which the reaction is carried out; when, for example, finely-divided strychnine (10 parts) is heated at $50\text{--}55^\circ$ with a solution of sodium (1 part) in alcohol (10 parts), strychnic acid alone is formed; but if the temperature is raised to 70° , the product contains small quantities of isostrychnic acid.

Strychnic acid is completely converted into strychnine when it is heated at 190° in a stream of hydrogen; its other properties have been already described by Loebisch and Schoop. The *nitrosamine hydrochloride*, $\text{C}_{20}\text{H}_{22}\text{NO}(\text{COOH})\cdot\text{N}\cdot\text{NO}\cdot\text{HCl} + \text{H}_2\text{O}$, is obtained when the acid is treated with sodium nitrite and hydrochloric acid in the cold; it crystallises from alcohol in yellowish prisms, is moderately easily soluble in cold water, and gives the nitroso-reaction; on reduction with zinc dust and acetic acid, it is converted into a compound which reduces Fehling's solution, but when warmed with tin and hydrochloric acid it yields strychnic acid hydrochloride.

Strychnic acid methiodide, $\text{C}_{21}\text{H}_{24}\text{N}_2\text{O}_3\cdot\text{MeI} + \text{H}_2\text{O}$, is formed when an aqueous solution of the sodium salt of strychnic acid methiodide (see below) is acidified with dilute acetic acid, and also when methylstrychnine (compare Tafel, *loc. cit.*) is treated with cold hydriodic acid; it loses its water at $120\text{--}130^\circ$, and is only very sparingly soluble in cold water and alcohol, and insoluble in ether, but it dissolves freely in alkaline carbonates. It gives a nitroso-derivative on treatment with nitrous acid, and, when boiled with dilute acids, it is converted into *strychnine methiodide*, $\text{C}_{21}\text{H}_{24}\text{N}_2\text{O}_3\cdot\text{MeI} + \text{H}_2\text{O}$. The *sodium salt*, $\text{C}_{21}\text{H}_{23}\text{N}_2\text{O}_3\cdot\text{Na} + \text{H}_2\text{O}$, prepared by heating strychnic acid with methyl iodide and alcoholic soda, or by dissolving the methiodide of strychnic acid in methyl alcoholic soda, crystallises in long needles, and is very readily soluble in water and methyl alcohol, but only sparingly in boil-

ing alcohol; the corresponding *silver* salt is a colourless, gelatinous, unstable compound.

Methylstrychnic acid methiodide, $C_{22}H_{26}N_2O_3.MeI + H_2O$, is obtained by treating an aqueous solution of dimethylstrychnine (*loc. cit.*) with hydriodic acid, and, also, together with its methyl salt, by heating a methyl alcoholic solution of the sodium salt of strychnic acid methiodide with methyl iodide. It crystallises from boiling water in small needles, loses its water at 130° , and is moderately easily soluble in hot alcohol, but insoluble in ether; when treated with a little silver nitrate and concentrated nitric acid, it gives the same blood-red coloration as dimethylstrychnine. The *methyl* salt, $C_{22}H_{25}N_2O_3.Me.MeI$, separates from boiling water in short needles, and is only sparingly soluble in alcohol and chloroform and insoluble in ether and benzene; when treated with freshly-precipitated silver oxide, it is converted into a strongly alkaline substance which is decomposed on boiling with formation of dimethylstrychnine.

Methylstrychnine (*loc. cit.*) is highly poisonous, and feebly lævoptatory; it gives the same colour reactions as strychnic acid. When treated with nitrous acid in aqueous solution, it is converted into a crystalline nitrosamine, and, when boiled with sodium ethoxide, it is transformed into a feeble base of the composition $C_{24}H_{30}N_2O_3$; this substance crystallises from boiling alcohol in small needles, melts at 158° , and is very readily soluble in benzene, chloroform, and glacial acetic acid, but almost insoluble in water.

A *nitroso*-derivative is obtained as a yellow precipitate when dimethylstrychnine (*loc. cit.*) is treated with amyl nitrite in alcoholic hydrochloric acid solution; it is a semi-crystalline, very deliquescent powder, and when dried at 100° in an atmosphere of hydrogen, it has the composition $C_{28}H_{38}N_2O_4.Cl_2$.

Isostrychnic acid, $C_{20}H_{22}NO(COOH).NH + H_2O$, is best prepared by heating strychnine (100 grams) with crystalline barium hydroxide (150 grams) and water (800 grams) at $135-140^\circ$, then filtering from unchanged strychnine, and saturating the hot filtrate with carbonic anhydride; the acid is extracted from the precipitated barium carbonate with dilute soda. The anhydrous compound is very hygroscopic, and takes up 1 mol. H_2O on exposure to the air; it resembles strychnic acid very closely, than which, however, it is rather more sparingly soluble in water. It gives the same colour reactions as strychnic acid, even after it has been boiled with acids, and it is not changed by boiling concentrated hydrochloric acid; it forms an oily acetyl derivative and an oily ethyl salt, and is highly poisonous. The *hydriodide*, $C_{21}H_{24}N_2O_3.HI + 2H_2O$, crystallises in well-defined prisms and loses 1 mol. H_2O over sulphuric acid in a vacuum, the other being expelled at 110° ; it is readily soluble in hot water, but only sparingly in cold water and alcohol, and insoluble in ether. The *nitrosamine hydrochloride*, $C_{21}H_{24}N_2O_4.HCl + 2H_2O$, crystallises from hot alcohol in needles, and is readily soluble in warm water, but insoluble in ether; it is decomposed by boiling water, gives Liebermann's reaction, and, when warmed with tin and hydrochloric acid, is decomposed, with formation of strychnine.

Isostrychnic acid methiodide, $C_{21}H_{24}N_2O_3.MeI$, can be prepared by

treating the sodium salt (see below) with dilute mineral acids, or by the action of hydriodic acid on an aqueous solution of isomethylstrychnine; it separates from hot water in crystals, is only sparingly soluble in alcohol, and insoluble in ether; when treated with nitrous acid, it yields a resinous nitroso-derivative. The *sodium* salt, $C_{22}H_{25}N_2O_3 \cdot Na + H_2O$, obtained by warming isostrychnic acid with methyl iodide and sodium methoxide in methyl alcoholic solution, crystallises from hot alcohol in microscopic needles, and is readily soluble in water.

Methylisostrychnic acid methiodide, $C_{22}H_{25}N_2O_3 \cdot MeI + H_2O$, is obtained, together with its methyl salt, by heating the sodium salt of isostrychnic acid methiodide with methyl iodide in methyl alcoholic solution, or by treating isodimethylstrychnine with hydriodic acid; it crystallises from boiling water in needles, loses its water at 130° , melts at 270 – 275° with decomposition, and is moderately easily soluble in hot alcohol, but insoluble in ether, chloroform, and benzene. The *methyl* salt, $C_{22}H_{25}N_2O_3 \cdot Me \cdot MeI + 2H_2O$, crystallises from boiling water in long needles, loses its water in a vacuum, and is very sparingly soluble in alcohol, and insoluble in ether and benzene; when treated with freshly-precipitated silver chloride, it is converted into the corresponding *methochloride*, $C_{22}H_{25}N_2O_3 \cdot Me \cdot MeCl + 2H_2O$, which crystallises in long, colourless needles.

Isomethylstrychnine, $C_{22}H_{25}N_2O_3 + 7H_2O$, is formed when an aqueous solution of isostrychnic acid methiodide is treated with silver oxide, first at the ordinary temperature and then at 100° ; it crystallises from hot water in small, colourless needles, and is very readily soluble in alcohol and hot water, but insoluble in ether and benzene; it yields a crystalline nitrosamine, and it gives the same reaction with dilute sulphuric acid and potassium dichromate as methylstrychnine, even after having been boiled with dilute acids.

Isodimethylstrychnine, $C_{22}H_{25}N_2O_3 + 3H_2O$, prepared from methylisostrychnic acid methiodide in like manner, or from the methylhydroxide of methyl methylisostrychnate, as previously described in the case of dimethylstrychnine (*loc. cit.*), separates from hot water in well-defined crystals, and is readily soluble in alcohol, but insoluble in ether; it gives the same reactions with oxidising agents and with nitrous acid as dimethylstrychnine.

The author's experiments have shown that the so-called hydrates of strychnine are isomeric imido-acids, that strychnine is an inner anhydride of strychnic acid, and that methyl and dimethylstrychnine are betain-like derivatives of this acid; the nitrogen atom in the $-CO-N-$ group in strychnine is in direct combination with one benzene nucleus.

F. S. K.

Constitution of Pseudoephedrine. By W. FILEHNE (*Virchow's Archiv*, 124, 95–96).—Of the three possible constitutional formulæ advanced by Ludenburg (Abstr., 1889, 1020) for this mydriatic alkaloid, the one he regards as most probable is

In this formula the amido-group stands in the β -position, and the substance would then be analogous to β -tetrabydrousaphthylamine

and phenylethylamine. The complete analogy now found for these substances, as regards their physiological action, confirms this supposition.
W. D. H.

Benzoylpseudotropeïne, an Alkaloid of Java Coca-leaves. By C. LIEBERMANN (*Ber.*, 24, 2336—2345).—The alkaloid was obtained in the form of its hydrobromide from Dr. Giesel, and was purified by extraction with ether and crystallisation from boiling water.

Benzoylpseudotropeïne hydrobromide, $C_8H_{14}NOBz, HBr$, crystallises in beautiful, long leaflets, and is soluble in water and alcohol.

Benzoylpseudotropeïne, $C_8H_{14}NOBz$, is obtained by decomposing the above salt with sodium carbonate and extracting with ether. On evaporating off the ether, it is obtained as an oil which solidifies in radiating crystals. It melts at 49° , reacts strongly alkaline in alcoholic solution, is easily soluble in alcohol, ether, chloroform, benzene, and light petroleum, and is optically inactive. The *hydrochloride*, obtained by passing hydrogen chloride into an ethereal solution of the base, crystallises in white needles, and melts at 271° . The *platinochloride* is obtained as a flesh-coloured precipitate, and is insoluble in water, alcohol, and ether. The *aurochloride* crystallises from water in beautiful, yellow needles, melts at 208° , and is sparingly soluble. Mercuric chloride causes a crystalline precipitate when added to a solution of the hydrochloride. Picric acids give a sparingly soluble precipitate, crystallising in yellow needles.

When the above base or its salts is heated with hydrochloric acid in a reflux apparatus for some hours, it is completely decomposed into benzoic acid and pseudotropine.

Pseudotropine, $C_8H_{14}NO$, is obtained from the products of hydrolysis of the above base after the benzoic acid has been extracted with ether. The acid solution is evaporated to dryness, and the hydrochloride either decomposed with silver oxide or excess of strong sodium hydroxide is added, and the base extracted with ether. It has a strongly alkaline reaction, crystallises in beautiful needles, melts at $106-107^\circ$, boils at $240-241^\circ$ (corr.), and is easily soluble in water, alcohol, and benzene, and is precipitated from the latter solvent by light petroleum. The base is, no doubt, identical with Ladenburg's pseudotropine, although the aurochloride melts at 225° , whereas Ladenburg's melted at 198° . The *hydrochloride* crystallises in needles, is somewhat hygroscopic, and easily soluble in alcohol. The *aurochloride* crystallises from water in beautiful, yellow needles, and is easily soluble in alcohol and hot water. The *platinochloride*, when first prepared, is so soluble that it is necessary to evaporate the solution almost to dryness before crystallisation takes place; the crystallised salt is, however, difficult to dissolve in water, and is precipitated on the addition of alcohol. Pseudotropine hydrochloride yields, with mercuric chloride, a white precipitate; with picric acid, an easily soluble salt, crystallising in yellow needles.

The author has synthesised benzoylpseudotropeïne by heating pseudotropine (3 grams) with water (1.5 grams) and benzoic anhydride ($1\frac{1}{4}$ mols.) on the sand-bath for $1\frac{1}{4}$ hours at the boiling point

of the mixture. The synthetical base is entirely similar to the natural one.

The author has no doubt that a series of pseudotropeïnes, corresponding to the tropeïnes, can be prepared from pseudotropine. He has prepared the following:—

Cinnamylpseudotropine, $C_8H_{11}NO(C_9H_7O)$, is obtained from pseudotropine and cinnamic anhydride, melts at $87-88^\circ$, and is very easily soluble in cold alcohol, ether, and benzene, somewhat less so in light petroleum. The *hydrochloride* is obtained as a white, crystalline precipitate on passing hydrogen chloride into an ethereal solution of the base, and is easily soluble in alcohol and ether. The *picrate*, *platinochloride*, and *aurochloride* are similar to those of benzoylpseudotropine.
E. C. R.

Alkaloids of *Corydalis cava*. By F. ADERMANN (*Chem. Centr.*, 1891, i, 978—979).—The dried and ground-up roots of *Corydalis cava* are extracted with 80—85 per cent. alcohol at 25° , the alcohol evaporated under diminished pressure, and the residue extracted by Dragendorff's method. Benzene extracts considerable quantities of crystalline substances, both from the acid, and also from the alkaline liquid. The alkaline liquid may be extracted firstly with light petroleum, and then with chloroform, the latter extracting an alkaloid. Ether extracts alkaloids from the acid liquid, and if, after separating the ether, the solution be extracted with chloroform, a base is obtained which is identical with that obtained from the alkaline liquid with the same reagent. The author isolated three bases. The first is isomeric with the hydroberberine of Court, $C_{20}H_{21}NO_4$, and is oxidised by chromic acid to berberine. It differs from Court's hydroberberine in the melting point, 138° , and in its optical properties; it is a tertiary monamine.

The chloroform extract of the *Corydalis* alkaloids includes one which is similar to caffeine; its formula is $C_8H_{11}NO_4$. It reacts with concentrated sulphuric acid, forming a yellowish coloration, which passes, slowly in the cold, rapidly when warmed, into a beautiful violet. Erdmann's reagent causes a brownish-red coloration, Fröhde's, a violet, or green streaked with reddish-violet; selenium sulphuric acid, a light violet; nitro-sulphuric acid, a bluish-violet; and potassium dichromate and sulphuric acid, a similar coloration to strychnine. If the solution of the base be covered with concentrated hydrochloric acid and chlorine water added, a red zone is formed, and, after shaking the mixture the whole solution becomes pink-coloured. The author names this base *corydaline*. It resembles Reichwald's fumarine, $C_{21}H_{19}NO_4$ (Abstr., 1890, 272), in some respects, but differs from it in being optically active and in its solubility. The third base which the author extracted was not obtained crystalline, but reacted with the several alkaloid reagents.
J. W. L.

New Alkaloid in *Tylophora asthmatica*. By D. HOOPER (*Pharm. J. Trans.*, 21, 6—7).—The inspissated alcoholic extract of the root of *Tylophora asthmatica* treated with water gives a solution which, after filtration, is made alkaline with ammonia, and agitated

with ether to extract the alkaloid *tylophorine*. This, on evaporating its ethereal solution, is left in the form of crystals, sparingly soluble in water. The ethereal and alcoholic solutions have an alkaline reaction, and the substance forms with acids neutral solutions, from which it is precipitated by all the usual alkaloidal reagents. The *nitrate* and *hydrochloride* form prismatic crystals. When added to sulphuric acid, the pure alkaloid is dissolved with colorations successively reddish-brown, red, green, and finally blue. Nitric acid colours it purple-red, dissolving some to orange solution; hydrochloric acid forms a yellow solution, Fröhde's reagent dissolves it with a sap-green coloration; and sulphuric acid and potassium dichromate produces a violet-brown liquid. It decolorises potassium permanganate, but is not affected by ferric chloride or lead acetate.

R. R.

Influence of Oxygen on the Formation of Ptomaines. By W. HUNTER (*Proc. Roy. Soc.*, 49, 376—379).—The interest attaching to the rôle of oxygen in the life history of bacteria led to this investigation of the quantity of ptomaines formed by means of putrefaction bacteria, (1) when oxygen was freely admitted; (2) when it was present in limited quantity; and (3) when it was withheld altogether. Such ptomaines as the diamines, formed in the early stages of putrefaction, are not poisonous, and contain no oxygen; in this respect they differ from those containing oxygen, like muscarine and neurine. Brieger concluded from this that free access of oxygen plays an important part in the formation of the poisonous bases, and favours the formation of ptomaines generally. The chief result of the present research is that the formation of ordinary putrefaction ptomaines is favoured by an entire absence of oxygen.

The ptomaines were isolated by Brieger's method, and in connection with the diamines accurate quantitative results were obtained by the use of benzoic chloride (the method of Baumann and Udránszky). The diamines formed during the early stages of the process (without oxygen, none being obtained if oxygen was admitted freely) disappear as putrefaction proceeds. No very definite results regarding toxic alkaloids were obtained; symptoms of poisoning were only obtained in one instance (eight experiments in all being made) from the injection of a fluid which had putrefied in the absence of oxygen.

W. D. H.

Peptotoxin. By E. SALKOWSKI (*Virchow's Archiv*, 124, 409—454). As a result of experiments on the digestion of proteids by means of pepsin, no poisonous substance soluble in water and amyl alcohol was formed, such as Brieger states he isolated from digested fibrin; in other words, a "peptotoxin" in Brieger's sense of alkaloidal substance does not exist.

If putrefaction is prevented, leucine and tyrosine are also never formed in gastric digestion.

If putrefaction be allowed to occur, poisonous basic products make their appearance. Some specimens of meat contain poisonous bases previous to the occurrence of digestion at all. The resinous substance present in commercial amyl alcohol (compare Udránszky, *Abstr.*, 1887, 1133) is also toxic. These facts no doubt explain Brieger's error.

That albumoses and peptones are toxic none will deny; the object of the present research is to show that their toxicity is one of their inherent properties, and not due to any basic product or toxine separable from them.

W. D. H.

Harnack's Ash-free Albumin. By B. WERIGO (*Pflüger's Archiv*, 48, 127—149; compare Absir., 1890, 272 and 392). The so-called ash-free albumin obtained by Aronstein and Schmidt by means of dialysis was shown by later observers (Heynsius, Winogradoff) to be poor in ash, but not free from ash, and, moreover, that its characteristic properties (uncoagulability by heat, solubility in water, &c.) were due to the use of alkali in its preparation. Harnack has lately taken up the question again, and prepared a proteid substance practically free from ash, by precipitating it by means of hydrochloric acid from a solution of copper albuminate in sodium hydroxide. This material agrees in its properties with the substance obtained by Aronstein. The present researches first show that in his main facts Harnack is quite correct, the only point of difference being that in order to precipitate the ash-free proteid, it is necessary to add excess of hydrochloric acid; mere neutralisation precipitates only the copper albuminate. Further investigation of the ash-free proteid showed that it is not coagulable by heat, but that it is precipitated by neutralisation, the precipitate being soluble in excess of either acid or alkali; in other words, the substance which Harnack describes as ash-free albumin is only a derivative of albumin, which resembles in its properties the well-known derivatives called acid-albumin and alkali-albumin.

In Harnack's case one deals with an acid solution, in Aronstein's with an alkaline solution, of this albuminate; this accounts for a difference which must be noted in the two cases. The reaction sufficiently explains this fact, which is that Harnack's substance is, and Aronstein's is not, precipitable by neutral salts. Aronstein's substance, however, like all these albuminates, is coagulated by heat when their solutions are saturated with such neutral salts.

The next question which arises is whether Harnack's derived albumin is formed by the alkali and acid used in the latter parts of the process of preparation, or previous to this. A number of considerations, none, however, absolutely proving the point, appear to show that the change occurs prior to the use of the alkali and acid; or, in other words, that Harnack's copper albuminate is strictly analogous to the albuminates known as acid- and alkali-albumin respectively; in the one case copper, in the other case acid and alkali are in union with the proteid molecule. It has already been stated that in the preparation of Harnack's albuminate it is necessary to add excess of acid; whereas after its preparation it is readily soluble in slight excess of acid. This difference is due to the fact that during the addition of hydrochloric acid to the sodium hydroxide solution sodium chloride is formed; and it is the presence of this salt which renders the albuminate insoluble in the excess of acid; this is true for acid-albumin generally.

Weighted quantities of Harnack's albuminate were then subjected

to titration, the quantity of standard acid and alkali necessary to precipitate and redissolve the precipitate being noted. From these the amount of sodium present in the alkali-albuminate was calculated, the average of six experiments showing a percentage of 0.969. Two atoms of sodium in the molecule, taking Harnack's estimation of the molecular weight of albumin (4740.8) as correct, would amount to 0.97 per cent. Harnack's copper albuminate, however, is stated to contain 2 atoms of copper; the sodium compound, if analogous, should therefore contain 4 atoms of sodium.

Further experiments showed that in some cases for precipitation and re-solution two equivalents of alkali correspond to one of acid, and a number of arguments are advanced for and against the contention that Harnack's formula should be doubled; the facts are, however, not irreconcilable with the assumption that Harnack's formula is correct; and there appears to be no doubt that acid and alkaline albuminates are definite chemical compounds. W. D. H.

Behaviour of Albumin when Subjected to Pressure. By A. DENAËYRE (*Chem. Centr.*, 1891, i, 509; from *Compt. rend. Stat. Sci. Brasserie de Gand*, 1 Heft).—Albumin, when heated under pressure either in water or in dilute acids, undergoes changes. When heated in water under a pressure of one atmosphere, it becomes soluble again and reacts as uncoagulated albumin. At higher pressures other changes take place, the solution becomes more perfect, and leucine and tyrosine are formed. At very high pressures, for instance, 10 atmospheres, the solution becomes alkaline, and ammonia derivatives and amido-acids are formed. A small quantity of albumose, precipitable by ammonium sulphate, has been detected as a result of the action, but no peptone. The albumin of egg, muscle, blood, and milk casein all behave similarly under these conditions.

Treatment with dilute hydrochloric acid causes a simple solution of albumin; by boiling it with 10 per cent. hydrochloric acid, a solution is obtained from which nitric acid causes no precipitation, nor is the albumin precipitated after neutralising the acid with soda or potash. By heating the albumin with 5 per cent. hydrochloric acid under a pressure of one atmosphere for one hour, a similar solution is obtained. This modification the author names *α -acid albumin*. If the heating be continued for two hours, or if the pressure be increased to 2 atmospheres, a clearer solution is obtained which is neither precipitated by boiling nor by nitric acid, but is precipitated by neutralising the acid; this modification has been named *β -acid albumin*. No peptone could be detected. They are similar to syntonin. At higher pressures considerable quantities of ammonium chloride and chlorine derivatives of the amido-acids are formed. J. W. L.

Physiological Chemistry.

Human Respiration, Air being Re-breathed in a Closed Vessel. By W. MARCET (*Proc. Roy. Soc.*, 49, 103—117).—The following are the results obtained in the present enquiry:—

1. On re-breathing air in a closed vessel, less carbonic anhydride is expired within a given time than in ordinary breathing, the volume of the air undergoing at the same time a slight reduction.

2. When fresh air is taken after re-breathing air in a closed vessel, the volumes of air breathed and the weights of carbonic anhydride expired are greater than in ordinary breathing; this, however, passes off in a few minutes.

W. D. H.

The Respiratory Exchange of Gases. By W. MARCET (*Proc. Physiol. Soc.*, 1891, 33—35).—A number of data concerning the amount of gases inspired and expired by human individuals are given. They were obtained by the use of the author's own apparatus. The mean respiratory quotient in 22 experiments was 0.87. The influence of food and fasting on the amount of gases respired is also illustrated. In five experiments, each lasting five minutes, the air inspired contained 3 to 4 per cent. of carbonic anhydride. Under these circumstances, the amount of oxygen consumed is greater, while the carbonic anhydride expired is very much less, than in ordinary breathing.

W. D. H.

Action of Paraffinic Nitrites on Blood Pressure. By J. T. CASH and W. R. DUNSTAN (*Proc. Roy. Soc.*, 49, 314—319).—Amyl nitrite is the one on which most of our knowledge at present rests. This and other nitrites of the paraffinic series were prepared pure for the present research by the reaction of the corresponding alcohol, previously purified, with sodium nitrite in the presence of dilute acid. The blood pressure was recorded by means of a modification of the ordinary kymograph, by which it was possible to record a long tracing on a slowly revolving drum, and shorter tracings at intervals on a rapidly revolving cylinder. By means of experiments on cats and rabbits, it was shown that the well-known effect of a fall in blood pressure produced by amyl nitrite is due to the direct action of the drug on the vascular walls causing the vessels to dilate (Brunton, Mayer, and Friedrich), and not to its action on the vaso-motor centre (Filehne). These experiments fall into two categories; in the first, the head was cut off from the circulation, and amyl nitrite still gave rise to as great a fall of pressure as when the head was included in the circulation. In the second series, the drug was injected into the carotid artery, but prevented from reaching the general circulation by appropriate ligatures. The fall of pressure did not occur until these ligatures or clamps were removed.

In experiments on man, a special nose and mouth piece was devised to enable a known quantity of the nitrite to be inhaled. The order of activity (that is, extent of pulse acceleration, which is greatest in

neurotic individuals) for various nitrites is :—(1) α -amyl; (2) β -amyl; (3) isobutyl; (4) secondary butyl; (5) primary butyl; (6) secondary propyl; (7) primary propyl; (8) ethyl; (9) methyl.

A broad summary of the action of the nitrites is as follows :—

All produce a fall of blood pressure, and an accompanying acceleration of the pulse; the latter is not so marked after intravascular injection as after inhalation, and is also less marked in cats than in men. The respiration is affected temporarily during inhalation in various degrees by the different nitrites, and permanently by repeated administration of the same or different nitrites.

The activity of the nitrites, as measured by the fall in blood pressure after inhalation, is as follows :—(1) secondary propyl; (2) tertiary butyl; (3) secondary butyl; (4) isobutyl, nearly equal; (5) tertiary amyl; (6) α -amyl; (7) β -amyl, nearly equal; (8) methyl; (9) butyl; (10) ethyl; (11) propyl. After intravascular injection, however, the order is nearly the reverse. The causes of these differences will be considered in a later paper.

W. D. H.

Influence of Temperature on Digestive Ferments. By E. BIERNACKI (*Zeit. Biol.*, 28, 49—71).—Digestive ferments require for their efficient action a certain reaction and a suitable temperature. The *optimum* temperature is 39—40°, that is, a little over that of the body. Higher temperatures destroy the ferment, and the present research is occupied with the determination of the temperature necessary for this latter purpose.

The first ferment investigated was trypsin, and it was found that 45° C. markedly lessens its activity, and exposure for five minutes to 50° destroys it altogether. The specimens of trypsin employed were some pure, some impure, and certain exceptions to the above stated rule were noted. It being very improbable that various trypsins differ in this particular, in virtue of their inherent characters, experiments were instituted to determine the factor that caused the difference. It was found that small admixtures with certain salts had the power of increasing the resistance of the ferment to temperature; the activity of the ferment was often lessened by the salt (although this was more marked in the case of pepsin), but the *optimum* temperature was 50°; 55° lessened, and 60° destroyed, the activity of the ferment. The salts which acted thus were ammonium sulphate (a salt used in the preparation of some specimens of ferment used in the preliminary experiments), ammonium chloride, phosphate, and nitrate, and sodium chloride. If mixtures of two or more of these salts were used, the effect was more marked still.

Certain salts (ammonium carbonate and oxalate, magnesium sulphate, sodium sulphate and phosphate), starch, and sugar had no such action, but certain products of proteolytic activity (albumose, amphotone, and antipeptone) act like the salts just enumerated. All the materials that act in this way increase the alkalinity of the digesting medium; minute doses of sodium hydroxide act in a precisely similar way, and the proposition is advanced that the whole of the phenomena are simply dependent on the reaction. Increase of alkalinity protects the ferment. It was found that increase of acidity (trypsin will act

in an acid medium if salicylic acid be employed) acts in exactly the opposite way; in an acid medium, 33—35° is the *optimum* temperature; 40° hinders, and 45° destroys, the action of the ferment.

Pepsin was then investigated, and it was found that acidity acts towards this ferment precisely like alkalinity towards the tryptic ferment, the temperature necessary to destroy its activity rising from 65° to 70°. In a neutral medium, the temperature falls to 55°.

Unfiltered fresh saliva loses its diastatic properties at 75°, filtered saliva at 70°, diluted saliva at 60°, pure ptyalin at 70°, unless its solution is much diluted, when the necessary temperature sinks to 60°. The influence of salts, reaction, &c., is exactly the same in kind as with trypsin. In all cases, if the pure ferment be used, the influence of temperature and the influence of salts, &c., on the temperature are more easily observed than if the ferment be impure, as contained, for instance, in the digestive juice.

The explanation of these occurrences probably lies in the formation of loose compounds with the enzymes, analogous to the pepsin-hydrochloric acid of Schmidt and other authors.

W. D. H.

Action of Pancreatic and Rennet Extracts on Casein. By J. S. EDKINS (*Brit. Med. J.*, i, 1891, 1332—1333, and *J. Physiol.*, 12, 193—219).—Milk is occasionally clotted by pancreatic extracts; but even if this does not occur, the casein in the milk (that is, caseinogen, W. D. H.) will be altered so that boiling causes a curdling of the milk. The casein thus altered has been termed meta-casein (Roberts). The existence of meta-casein is, however, transient. Its appearance is not due to the combined action of heat and fatty acid liberated by the pancreatic juice, as no change in reaction occurs if the juice used has lost its ptyolytic properties, and yet meta-casein appears. Meta-casein appears to be casein of which the precipitation is hindered in the cold by the concomitant action of trypsin. Meta-casein may be separated from milk by half saturation with certain neutral salts. Its reactions suggest affinities to casein rather than caseinogen. Whey proteid appears to come into existence simultaneously with the appearance of meta-casein.

W. D. H.

Influence of Alcohol on Proteid Metabolism. By R. H. CHITTENDEN, C. NORRIS, and E. E. SMITH (*J. Physiol.*, 12, 220—232).—As the result of three experiments on dogs, the conclusion is drawn that alcohol has no striking action on the general metabolism of proteid matter. In each case they extended for eight or ten days, and the quantity of alcohol used was large, rising to 2.5 c.c. per kilo. of body weight. At the same time alcohol has some specific action on nutrition, as manifested in its tendency to increase the excretion of uric acid in proportion to urea.

W. D. H.

The Proteid Requirement of Healthy Men. By STUEDEMUND (*Pflüger's Archiv*, 48, 578—591).—Voit gives the following daily diet as a minimal one for a full-grown man: 118 grams proteid, 56 grams fat, and 500 grams carbohydrate. Since his time various observers have given other numbers; most interest attaches to the daily proteid

requirement, and various authors give numbers from 110 to 35 grams. These variations are in part due to the fact that the number of individuals on whom the observations were made was small, being often limited to the experimenter's own person. It is impossible to deduce an average diet from such observations, but it is necessary to experiment on large numbers of persons. Accordingly, in the present research, continuous observations on 47 recruits in the army were made. These lasted for nearly four months. The experiments involved daily examination of the food and body weight; the food included the ordinary rations, the purchases of the recruits, and the packages of eatables they received from their homes. In this way, all were not on precisely the same diet, but the results are all averaged up, and the daily mean diet was thus, 113 grams proteid, 54.3 fat, and 551.8 carbohydrate. At the end of the period, 34 of the men had gained in weight, five had lost weight, and three were the same as at the beginning; one died, and the remaining four did not continue the experiment. On the average each man gained 3.5 kilos. in weight, or 38 grams per day. This increase of weight was doubtless due chiefly to growth of muscle (the daily exercises of these men are given); and thus 76 grams or 20 per cent. of the increased weight may be taken as the amount of new proteid put on daily; this would reduce the daily requirement of proteid food to 105.4 grams, which is a smaller number than that given by Voit as the amount necessary to keep the body in equilibrium.

W. D. H.

Nutrition of Muscle. By J. BRINCK (*Brit. Med. J.*, ii, 1891, 181—183).—The object of these experiments was to test on skeletal muscle the nutritive action of various proteid fluids in continuation of the results which Kronecker and his pupils have obtained on cardiac muscle (*Abstr.*, 1889, 632). These results are to the effect that solutions of myosin, syntonin, peptone, casein, egg albumin, and glycogen are incapable of restoring to activity the "washed out" frog's heart, and that serum albumin is the only known nutritive proteid. Ringer attributes the resuscitating effect of a circulating fluid to its inorganic salts, and Mays (*Practitioner*, 39, No. 4) to creatine and its allies.

A "washed out" heart is one perfused by normal saline, until it ceases to respond to strong induction shocks, not when it ceases to contract spontaneously. Ringer apparently uses the word in the latter sense, and his results are explained by regarding his solutions as stimulant, not nutritive. The present experiments made with the sartorii of the frog lend support to Kronecker's conclusion that the proteids of serum (spoken of in the authoress's paper roughly as serum albumin) are nutritive, and that other proteids, salts, and extractives are not.

W. D. H.

Effect of Partial Extirpation of the Kidneys on Nutrition. By J. R. BRADFORD (*Proc. Physiol. Soc.*, 1891, 18—20).—Dogs were fed on a known diet, and the daily amount of urine and urea determined. The total nitrogen of ingesta and excreta was determined by Kjeldahl's method.

A wedge-shaped portion of one kidney was removed antiseptically, and after the healing of the wound, the animal is apparently normal. The kidney wound heals by the first intention. From a fortnight to six weeks after this first operation, the whole of the second kidney was removed. The animal rapidly emaciates; its temperature falls, and death ensues from two to six weeks after the second operation. The urine contains no albumin or sugar, but the most remarkable effect observed is that the animal which only retains a fragment of one kidney secretes a markedly increased amount of urine, of urea, and of total nitrogen. If, however, the fragment removed at the first operation is small, so that less than about three-quarters of the whole kidney weight is removed at both operations, there is no increase in urea, but merely in the water excreted; the animal emaciates but slightly and lives much longer.

The fragment of kidney found *post mortem* is distinctly atrophied.

Corresponding with the increase of urea in the urine, there is an increase also in the blood (here it may be quadrupled), muscles, liver, and brain. Control experiments with normal dogs were made.

W. D. H.

The Influence of Sodium Chloride in the Chemical Composition of the Brain. By I. NOVI (*Pflüger's Archiv*, 48, 320—335).—The injection of a 10 per cent. solution of sodium chloride into the carotid artery leads to a loss of water in the brain, which is especially marked in the cortex. Less than 1.25 per cent. of the total amount of water in the brain is thus lost after one injection, but after injections repeated at intervals, the loss may amount to 5 per cent. The normal amount of sodium in the brain rises, that of potassium falls; the sum of the two metals is, however, almost constant. This is especially the case if one considers the brain as a whole; in the grey matter, the greater metabolic activity leads to variations within somewhat wider limits. In the whole brain, the sodium rises from 0.09 to 0.32, and the potassium falls from 0.39 to 0.25 per cent. The percentage of chlorine also rises, for sodium requires more chlorine to saturate it than the same weight of potassium. To these changes the convulsions that occur are probably due. It was also noted that other effects were a clear red colour of the venous blood, and an excitability of muscular and nervous tissues, lasting many hours after death.

W. D. H.

Deposits of Iron and Glycogen in the Tissues. By S. DELÉPINE (*Proc. Physiol. Soc.*, 1891, 35—39).—The most convenient micro-chemical test for so-called "free iron" in the tissues is the Prussian blue reaction. The specimens are first placed in a 5 to 10 per cent. solution of potassium ferrocyanide, washed in water, and lastly, for a period varying from a few minutes to a few hours, in a 0.5 to 1 per cent. solution of hydrochloric acid.

Hæmoglobin does not give the test; and the term "free iron" is apparently used for loose combinations of iron with nuclein or other albuminous material deposited in the cells, and generally colourless, although in the kidney it occurs in the form of brownish granules. The kidney gives the test more readily than the liver; the organs

used were from a case of doubtful pernicious anæmia. The liver, however, gives the reaction well after a few days immersion in alcohol and glycerol, which are considered to produce a loosening of the union between the iron and the organic compound. The conclusion is drawn from this that the iron is more firmly combined in the liver than in the kidney cells.

A new method recommended for the making of permanent specimens to show deposits of glycogen or lardacéin in cells is the following:—The sections are washed with a solution of iodine in chloroform, dehydrated with alcohol, cleared with clove oil, and mounted in chloroform balsam coloured with iodine. W. D. H.

Lecithin in the Liver. By A. HEFFNER (*Chem. Centr.*, 1891, i, 459; from *Inaug. Diss. Leipzig*, 1890).—The author finds that the amount of lecithin present bears a definite relation to the weight of the liver, that an alteration of food does not affect this, but that the proportion decreases during a long fast. Phosphorus poisoning is accompanied by a material decrease, upwards of 50 per cent., in the quantity of lecithin in the liver, and the decrease is the greater the more fatty the liver. The author considers that this is occasioned by the direct decomposition of the stored-up lecithin. J. W. L.

Composition of the Bones of Aged Rabbits. By L. GRAFFENBERGER (*Landw. Versuchs-Stat.*, 39, 115—126).—Hitherto the composition of the bones of rabbits of 6—8 years old has not been made known. The author now communicates the complete composition of the bones of a buck 6½ years old and a doe 7½ years old.

The results as stated, accompanied by full analytical details, are: water and fat decrease with increasing age; there is no change between the ratios of organic to inorganic matter: old rabbits' bones contain more carbonate but less phosphate of lime than the bones of the young animals, 2—4 years. E. W. P.

Amount of Fat and Dry Matter in the Milk of some Hill-bred Cows. By J. SINDLER (*Biol. Centr.*, 20, 393—394; from *Wien. landw. Zeit.*, 41, 166).—Milk of cows of the Pinzgau, Mürzthal, and Murboden breeds was examined. The cows were kept for several weeks on the same food. The daily feeding was:—Malt (1·8 kilos.), wheat bran (1·8 kilos.), clover hay (3·5 kilos.), meadow hay (10 kilos.), and salt (25 grams). The cows were fed three times daily, and the specially good ones were milked three times daily. The average composition of the milk from the different breeds was as follows:—

Breed.	Daily yield.	Sp. gr.	Fat per cent.	Dry matter per cent.
Murboden	8·9 litres	1·0330	4·05	13·24
Mürzthal	10·4 „	1·0318	3·58	12·48
Pinzgau	7·4 „	1·0338	3·78	12·08

Owing to the cows of the first two breeds having been specially selected as good milking cows, and to the different ages of the cows,

no direct comparison with regard to the yield of milk can be made. The average weight of the Murboden and Mürzthal cows was 580 kilos., whilst the weight of the Pinzgau cows varied from 400 to 500 kilos. N. H. M.

Citric Acid a Normal Constituent of Milk. By T. HENKEL (*Landw. Versuchs-Stat.*, 39, 143—151).—To obtain citric acid from milk, freshly separated milk was curdled with a strong solution of rennet, the casein separated, and then 10 c.c. normal acetic acid and 10 grams "Spanish-earth" per litre were added, and the mixture boiled, filtered, and neutralised with milk of lime. On concentrating the filtrate, a powdery precipitate is formed, which, when washed first with water, and then with ether alcohol, gave all the reactions for calcium citrate. More especially was the reaction with Sabanin-Laskowski's reagent marked, this reagent being only active with citric and aconitic acids. Experiments showed that citric acid existed in the milk, and is not produced or introduced by the rennet, so that it must be considered as a normal constituent. E. W. P.

Origin of Citric Acid in Milk. By A. SCHEIBE (*Landw. Versuchs-Stat.*, 39, 153—170).—The source of citric acid in milk, as well as the various methods whereby it may be estimated, as also the experiments made which have given rise to the first method employed, are here detailed.

The source is still uncertain, for the acid is to be found in cows', goats', and woman's milk when food such as bread, peas, &c., has been supplied which contains no acid. Henkel (see previous paper) failed to find citric acid in human milk, but this was probably due to the fact that 1 milligram per litre of lactose prevents the Sabanin-Laskowski reaction from working.

As regards the method recommended for quantitative estimation, 400 c.c. of milk is mixed with 4 c.c. N. $2\frac{1}{2}$ sulphuric acid, boiled, and then 10 grams of "Spanish-earth," previously made into a paste with water, is added, boiled, and when cool made up to $\frac{1}{2}$ litre. To 100 c.c. of filtrate (= 80 c.c. milk), baryta-water is now added to bring back the milk to its usual acidity, and then evaporated to a syrup, but just before this syrup is quite cool 3.2 c.c. N. $2\frac{1}{2}$ sulphuric acid is added, to set the citric acid free 20 c.c. of absolute alcohol is gradually added, and later on 60 c.c. of ether, the liquid filtered, and the residue (lactose) washed with ether alcohol. To the filtrate, alcoholic ammonia is added until a permanent opalescence is produced, and the ether distilled off until only 20 c.c. of residue is left, to which 60 c.c. of absolute alcohol is added. It is now heated to boiling on a water-bath, and then 10 c.c. of alcoholic ammonia added, whereby the citric acid is completely precipitated. This precipitate contains, besides ammonium citrate, ammonium sulphate and phosphate and a small amount of chloride, and a trace of organic matter, all of which may be removed by a second precipitation; add 1 c.c. N. $2\frac{1}{2}$ sulphuric acid and 1 c.c. water, then add 60 c.c. of absolute alcohol, and precipitate with 10 c.c. of alcoholic ammonia; as it requires a long time for the liquid to clear, it is advisable to add ammonium carbonate

and heat in a retort with a reflux condenser, then filter, and wash with absolute alcohol; now dissolve the citrate in 20 c.c. water, add excess of a titrated solution (20—30 c.c.) of potassium dichromate (46.1 grams per litre) and 20—25 c.c. of concentrated sulphuric acid; heat (not boil) for $\frac{1}{2}$ hour. Dilute the brownish-green solution with 50 c.c. of water, add excess of titrated solution of ferrous ammonium sulphate until a clear green is produced, and then titrate back, the final reaction being noted by potassium ferricyanide. 4.61 grams of dichromate are equivalent to 1 gram of citric acid.

To detect citric acid qualitatively, the precipitate formed after heating with ammonium carbonate is dissolved in water, evaporated to 1 c.c., 3 c.c. of a concentrated solution of ammonia added, and then finally the Sabanin-Laskowski reagent.

In human milk, 0.54 gram citric acid per litre has been found; this is about half of that in cows' milk, whilst in goats' milk 1—1.5 gram per litre has been estimated. E. W. P.

Nitrogenous Substances in Human Urine. By W. CAMERER (*Zeit. Biol.*, 28, 72—104; compare Abstr., 1890, 1345).—The total nitrogen in human urine is dependent on the amount ingested; the relation between urea, uric acid, and xanthine-like substances is also largely a matter of diet. The present paper is devoted to the elucidation of the latter statement.

The analytical data determined were:—(1) total nitrogen; (2) Hüfner nitrogen, that is, the nitrogen of urea and ammonia; the difference between (1) and (2) may be called the nitrogen residue; (3) uric acid *a*, that is, uric acid by Salkowski's method; (4) uric acid *b*, that is, uric acid by Ludwig's method; the difference of the nitrogen of (3) and (4) gives the nitrogen of the xanthine-like substances.

The experiments were made on the author's person, and the following diets were taken for periods of a few days:—A. Pure animal diet. B. Almost pure vegetable diet. C. Vegetarian diet with excess of green vegetables. D. Mixed diet, but without fruit or green vegetables. On some days 1500 c.c. of wine were taken; on others not, but this made practically no difference.

The results are given in full tables; the following abbreviated table gives means only *per diem*:—

Diet.	Total nitrogen.	Hüfner nitrogen.	Nitrogen residue.	Uric acid <i>a</i> .	Uric acid <i>b</i> .	Nitrogen of xanthine-like compounds.
A	17.85	16.66	1.19	745	693	17.6
B	8.61	7.48	1.13	600	508	30.7
C	7.73	6.63	1.10	539	397	47.3
D	13.42	11.85	1.57	712	603	36.4

The absolute nitrogen residue is thus almost independent of the amount of proteid taken in; but the relative nitrogen residue is

greater with the smaller ingestion of proteid. The nitrogen of xanthine-like substances is almost independent of the total nitrogen, and is especially increased by vegetable, and particularly by green vegetable, diet.

A number of analyses are also given contrasting summer and winter urine and male and female urine. The differences are all explicable on the very reasonable assumption that more fruit and green vegetables are eaten in the summer than in the winter, and more by women than by men. The xanthine substances are apparently formed at the expense of the uric acid.

The paper concludes with statistics on the relation of the nitrogen residue to urea, and criticisms on methods of analysis.

W. D. H.

Urobilin in Various Diseases. By G. HOPPE-SEYLER (*Virchow's Archiv*, 124, 30—47).—For comparative purposes, the amount of urobilin in urine may be estimated in the following way:—100 c.c. of urine is acidified with dilute sulphuric acid, and then saturated with ammonium sulphate. This salt precipitates all the urobilin. The red flocculi are collected on a filter, washed with concentrated ammonium sulphate solution, and extracted with equal parts of alcohol and chloroform in a flask, filtered, and the residue is then again extracted with the alcohol and chloroform; water is added to the extract until the chloroform separates. The chloroform solution is then evaporated in a weighed beaker over the water-bath, dried at 100°, extracted with ether, and filtered; the residue is again dissolved in alcohol, placed again in the beaker, evaporated, dried, and weighed.

The urobilin in the urine is increased by:—

(1.) Stasis of the bile in the liver, provided bile can pass into the intestine, and diuresis occurs, as in polycholia.

(2.) Stagnation of the contents of the large intestine, not of the small intestine.

(3.) Hæmorrhages into internal organs.

Approximately the normal amount is found in:—

(1.) Pernicious anæmia.

(2.) Leukæmia and pseudoleukæmia.

It is diminished in:—

(1.) The suspension of hepatic activity that occurs in cachexia, inanition, and many forms of anæmia.

(2.) Stasis of bile in the liver if bile does not pass into the intestine and no diuresis is produced.

(3.) In the course of jaundice, sometimes. The amount of faecal pigment is no gauge of the amount of urobilin in the urine.

The table given comprises particulars of 55 cases of various diseases, which are compared with 8 normal specimens. The normal mean amounts to 0.123 gram in the 24 hours.

W. D. H.

Note by Abstractor.—A good deal of interest attaches to the amount of urobilin in pernicious anæmia. In the single case examined in this research, the amount calculated as being present in the 24 hours' urine is 0.107 gram. One cannot safely draw

general conclusions from a single case (compare Abstr., 1888, 1324; 1890, 400, 1017, 1177). W. D. H.

Hæmatoporphyria. By W. D. HALLIBURTON (*Proc. Physiol. Soc.*, 1891, 21).—A case similar to those recently described (this vol., p. 601). It occurred in a woman suffering from melancholia, and who had been taking sulphonal for five months. The high-coloured urine had, however, only lasted for seven weeks. W. D. H.

Rhinoliths. By A. BERLIOZ (*J. Pharm.*, 23, 447—449).—Analyses of four rhinolithic calculi:—No. 1, the largest, had a wrinkled surface stained with black blood; the nucleus a cherry stone. No. 2 had a uniform brownish-black surface colour, and was pitted, but contained no nucleus. The third had a peculiar conical shape, with a kind of stalk attached to its base; its colour was whitish-yellow, and was without nucleus. The fourth resembled the second. They were all very hard and gave a smooth fracture. Their concentric layers had a greyish tint. Heated on platinum foil, they left an abundant residue, which was slightly blue in the case of Nos. 2 and 4. Their composition was as follows:—

	1.	2.	3.	4.
Weight of the calculus ..	3.75	1.34	0.63	0.95 grams.
Water	5.80	5.10	4.0	6.90 per cent.
Organic matter.....	16.60	18.20	16.0	18.10 "
Calcium phosphate.....	62.02	60.61	61.40	47.63 "
Magnesium phosphate....	5.08	6.28	3.93	6.68 "
Calcium carbonate.....	10.50	9.81	14.67	20.69 "

J. T.

Chemical Constitution and Physiological Action. By T. L. BRUNTON and J. T. CASH (*Proc. Roy. Soc.*, 49, 311—314).—In continuation of former work, the present research is occupied with (1) the physiological action of benzene, and (2) the alterations which occur in its action when one or more hydrogen atoms are replaced by (a) haloïd radicles, (b) alcohol radicles, (c) by hydroxyl, (d) by NO₂, and (e) by NH₂. The modifications produced by changes of temperature were also noticed.

The action of benzene and its compounds is chiefly exerted on the spinal cord, although they act also on the cerebrum, and, to a slight extent, on nerves and muscle. The effect on muscle and nerve is to weaken them, the paralysing action being stronger on the nerve than on the muscle. Their action on the cerebrum is evidenced by lethargy, both in frogs and rats. There is increased excitability of the spinal cord, there being greater diffusion of stimuli with diminished power and definitiveness of movement. Large doses, however, cause paralysis.

Haloïd radicles do not modify the action of benzene to the same extent as they do that of ammonia, but they do so in somewhat the same direction. Monochlorobenzene affects the cord more than benzene, causing spasm and rapid diminution of reflexes. It also

weakens the circulation, but does not seem to affect muscles, or motor nerves, more than benzene. The bromo- and iodo-compounds act more powerfully on the cerebrum, and the iodo-compound has a special tendency to paralyse motor nerves, muscles, and cerebral reflexes, and to depress the heart. Heat accelerates, and cold retards, the action of these substances.

The substitution of alcohol radicles for hydrogen in benzene has the effect which one would expect, in having a more sedative action on the nervous system. The circulation is little affected, and their action is more fleeting than is the case with the halogen compounds.

Substitution of hydrogen by hydroxyl increases the tendency to convulsions; this is due to action on the spinal cord.

Amidobenzene produces symptoms resembling those caused by ammonia, consisting in a tendency to produce violent spasm and great paralysis of muscle and nerve. It differs from ammonia in the fact that the convulsions never assume the form of true tetanus.

Nitrobenzene causes lethargy, with increasing tremor or movement, and early abolition of reflex action.

The general action of these compounds on reflex time is to lengthen it, but a primary shortening was frequently observed in the case of chlorobenzene, slightly also in that of methylbenzene, dimethylbenzene, and ethylbenzene.

In producing muscular rigor, chlorobenzene is more powerful than the bromo- and iodo-compounds, and is intermediate in effect between methylbenzene and dimethylbenzene. Of the methylbenzenes, the methyl- is the strongest, the dimethyl- next, and the trimethyl- weakest. Ethylbenzene is of nearly the same strength as methylbenzene in this respect.

In warm blooded animals (cats), respiration is early affected, there being a primary acceleration followed by slowing. The heart stops before respiration in poisoning by benzene and its haloid compounds, by ethylbenzene, amidobenzene, and nitrobenzene, whilst respiration ceases first in poisoning by the methylbenzenes and hydroxybenzenes.

The first effect of the benzene compounds on the pulse and blood pressure is a quickening and rise respectively; this is followed by a slowing and a fall.

W. D. H.

Action of Related Compounds on Animals. By W. GIBBS and E. T. REICHERT (*Amer. Chem. J.*, 13, 289—307; compare Abstr., 1890, 280, 813, and 1018).—*The Hydrazines*.—Phenylhydrazine hydrochloride depresses the cerebro-spinal centres, producing, in the frog, decreased sensibility and voluntary and reflex inactivity, merging into unconsciousness and paralysis. Death results from respiratory and cardiac failure, and the heart stops in diastole. In the dog, it acts at once on the heart, causing a preliminary quickening of pulse and lowering of blood pressure. The hæmoglobin is changed into an abnormal form, the blood becoming almost black. The temperature falls 1—2°. The respiration is at first quickened and then slowed, either by the action of the drug on the respiratory centres, or by the deficient oxygenation of the blood. The action of ortho- and para-

tolyldiazine hydrochloride is similar, but less pronounced. The fatal dose, when injected into the jugular vein of the dog, is 0.12 gram of phenylhydrazine hydrochloride, or 0.2 gram of orthotolyldiazine hydrochloride, per kilo. of body weight.

Toluylenediamine produces in the frog general muscular depression, but does not appreciably affect the sensory and motor nerves. The heart stops in diastole. Administered to the dog, it causes muscular depression, lowering of temperature, salivation, darkening of the blood, and diminution of the rate of respiration. The heart stops in diastole, and the stomach and intestines are found to be congested after death. Small doses of 0.8 gram per kilo., injected intravenously, increase the pulse rate, blood pressure, and respiration rate; the variation in the last is caused by direct action on the respiratory centres. The fatal dose for dogs is 0.2 gram per kilo. when injected subcutaneously; much larger doses may, however, be injected intravenously.

Nitrophenols—Dinitrophenol injected into the jugular vein of the dog in small doses of 0.2 gram per kilo. causes a stimulation of the vagus, proportional to the amount injected, and a rise in pulse rate and blood pressure. With larger doses (0.17 gram per kilo.), the heart stops before respiration ceases, and the blood pressure falls just before death. The minimum fatal dose is 0.05 gram per kilo. injected. When given by the mouth, the respiration rate at first rises, but subsequently falls, the temperature rises 2–3°, and the pulse rate first diminishes and then increases. The drug seems to act directly on the motor portion of the spinal cord. Death results from respiratory failure when the poison is slowly absorbed through the stomach, from cardiac failure when it passes in mass into the heart. Administered to the frog, dinitrophenol causes muscular depression, stops respiration, and discolours the blood, but the heart continues to beat for a long time after all other signs of life have disappeared. Trinitrophenol injected into the jugular vein of the dog stimulates the pneumogastric nerve or centres to such a degree as to cause the immediate stoppage of the heart. If the pneumogastric nerve is divided, death occurs from respiratory failure. The fatal dose is 0.06 gram per kilo. With the frog, the effect of progressively increasing doses is to stimulate a reflex activity, depress the heart, and stop the respiration. The fatal dose is 0.015 gram per kilo.

Nitrobenzenes.—Nitrobenzene acts on the spinal cord, causing in the frog increase in reflex activity, decrease in voluntary activity, and successive increase and decrease in pulse and respiration rates. The colour of the blood is changed to chocolate, the hæmoglobin being converted into nitrite-hæmoglobin. In the dog, when administered by the mouth, it produces salivation, unsteadiness of gait, rise of temperature and pulse rate, weakness, and unconsciousness; the respiration is quickened by a direct action on the respiratory centres. The animal may recover if the dose does not exceed 0.75 gram per kilo. When injected into the jugular vein, in which case the fatal dose is 0.15 gram per kilo., the blood pressure is diminished by the depression of the heart muscle and vaso-motor centres. The action of dinitrobenzene is similar, but more energetic.

Amides.—Formamide acts on the spinal cord, a dose of 0·3 gram per kilo. causing in the frog convulsions, paralysis, and death from failure of respiration. Injected into the jugular vein of the dog, it acts on the vaso-motor and respiratory centres, and on the cardio-inhibitory centres in the medulla oblongata, causing the blood pressure to fluctuate below and above the normal, checking the respiration, and slowing the pulse. Successive doses, amounting to 1·5 grams per kilo, permanently lower the blood pressure, and cause death from respiratory paralysis. Small doses (0·5 gram per kilo.) of acetamide introduced into the frog cause general relaxation and check the respiration; fatal doses (2 grams per kilo.) in addition increase the reflex activity and produce convulsions of spinal origin. When injected into the dog, the blood pressure is raised, and the rate of respiration is increased, whilst the pulse rate is diminished by the action of the cardio-inhibitory centres. Large doses (up to 5 grams per kilo.) may be injected with immunity, but these, after a time, cause extreme drowsiness and sleep. Propionamide introduced into the frog in doses of 0·5 gram per kilo. diminishes voluntary activity, and causes tetanic convulsions of spinal origin, followed by death. In the dog the effect is small; doses of 0·25 gram per kilo. strengthen the beat of the heart, lower the blood pressure, and act on the cardio-inhibitory centres, checking the pulse. Benzanilide diminishes sensibility and reflex and voluntary activity in the frog. The fatal dose is 1·0 gram per kilo. Administered to the dog, it produces the additional effects of staggering, salivation, lowered temperature ($1-3^{\circ}$), quickened respiration, and lessened pulse rate. Death results from failure of respiration. Injected into the jugular vein, it causes a rapid fall and rise in the blood pressure, but after repeated doses the pressure does not recover, and the heart is paralysed. The heart beat is lessened in force, the pulse becomes more frequent, and the respiration fails; at the same time, the pupils become dilated and sensibility is destroyed. The fatal dose is 0·5 gram per kilo. Oxamide, thiocarbamide, and pyromucamide have no appreciable effect on the dog.

Anilides.—Formanilide in the frog causes loss of sensibility and reflex and voluntary activity, muscular tremblings, convulsions of spinal origin, paralysis, and death. Administered to the dog by the mouth or subcutaneously in doses of 0·4 gram per kilo., it acts on the respiratory centres, quickening the respiration; on the cardio-inhibitory centres and heart, successively raising and lowering the pulse rate; and on the vaso-motor centres, lowering the blood pressure; it lowers the temperature, increases reflex activity, and produces feebleness and coma, and death from respiratory failure. Acetanilide given to the dog causes vomiting, weakness, lowering of temperature, quickening of pulse, darkening of blood due to formation of methæmoglobin, and cessation of respiration. When injected into the circulation, it acts on the heart, reducing the blood pressure and successively quickening and slowing the pulse. The rate of respiration at first increases, but ultimately diminishes and fails, causing death. The fatal dose is 0·3 gram per kilo. Benzanilide injected into the jugular vein of the dog at first increases the blood pressure,

but after the administration of several doses diminishes it. It also quickens the respiration and lowers the temperature. It is probable that the action of the drug is due to mechanical clogging of the capillaries of the nerve centres by the deposition of fine crystals, since enormous doses may be taken into the stomach without any appreciable effect.

JN. W.

Tuberculin. By W. HUNTER (*Brit. Med. J.*, ii, 1891, 169—176).—Koch's tuberculin was subjected to approximate analysis with the following results. In order of importance and amount the substances present are:—

(1.) Albumoses: chiefly proto-albumose and deutero-albumose, along with hetero-albumose, and occasionally a trace of dysalbumose. (2.) Alkaloidal substances, two of which can be obtained in the form of platinochlorides. (3.) Extractives, small in quantity and of unrecognised nature. (4.) Mucin. (5.) Inorganic salts. (6.) Glycerol and colouring matter. Serum albumin, globulin, and peptone are absent.

With regard to its action the following conclusions are drawn:—

1. Tuberculin owes its activity to at least three, and probably more, different substances.

2. Its remedial and inflammatory actions are connected with the presence of certain of its albumoses, whilst its fever producing properties are chiefly associated with substances of a non-albuminous nature.

3. The albumoses are not lost by dialysis; the latter are. It is thus possible to remove the substances which produce fever, while retaining those which are beneficial in their action. The fever is thus not essential to its remedial action, and the same may probably be said for the inflammation, although, under certain conditions, inflammation appears to be beneficial.

4. The remedial action consists in shrinking of the tuberculous tissues, and increased scaling, due to deep local congestions.

5. The remedial substance resists high temperatures. Its action is, however, lessened by a dry heat of 70°. Its properties are materially altered by changes occurring during its purification by dialysis, and thus its preparation is attended with difficulty.

6. The remedial substance and the other albumoses present are stated to belong to the class of "proteins," that is, albuminous substances derived from the protoplasm of the bacilli themselves, and not merely formed by the action of these bacilli on the surrounding tissues.

Various modifications of tuberculin were prepared, and lettered as follows:—

Modification A contains the total precipitate thrown down by absolute alcohol; it thus contains chiefly albumoses.

Modification C contains all the constituents of tuberculin not present in A.

Modification B contains the whole of the albumoses precipitated by the use of ammonium sulphate, the salt being subsequently removed by dialysis.

Modification CB was prepared from C, and contains the small amount of albumose which was not thrown down by the first precipitation with absolute alcohol. Salts were got rid of by dialysis. Koch is in error when he states that the remedial substance in tuberculin is easily diffusible. This modification is apparently the most satisfactory obtained, as it produces distinct local improvement, unattended with fever, and very little inflammatory action.

These modifications have been chiefly tested on cases of lupus. Further details respecting their therapeutic value are promised.

W. D. H.

Chemistry of Vegetable Physiology and Agriculture.

New Fermentation of Starch. By SOLAVO and GOSIO (*Bied. Centr.*, 20, 419; from *Arch. ital. Biol.*, 14).—Starch paste which had been kept for four months and had decomposed acquired an agreeable, fruity odour, due to the presence of alkyl butyrates, and subsequently an odour of valeric acid was perceptible. This starch paste was found to have the power of inducing the same change in other starch paste. The cause of this change is a bacillus (*Bacillus suaveolens*), which was isolated. The bacillus has no pathogenic properties, will develop on all the usual nutritive solutions, and presents a characteristic appearance in plate cultures; it does not liquefy gelatin. In order to develop spores, the bacillus requires air and a temperature of 22–29°, and a nutritive substance as neutral as possible. Acid is then produced to a certain limit (corresponding with 0.0676 per cent. of potash), when no more is formed. A trace of nitrogen is necessary for the nourishment of the bacillus. In milk, broth, hay extract, and aqueous extracts of straw and beetroot, the bacillus produces the same odour. It converts starch gradually into dextrin and glucose with formation of alcohol, aldehyde, formic, acetic, and butyric acids, together with ethereal substances of an agreeable odour.

N. H. M.

Fat and Ethereal Oil of Sabadilla Seeds. By H. OPIEZ (*Arch. Pharm.*, 229, 265–289).—The seeds, when extracted with light petroleum, yield a fat which is obtained on distillation of the extract in a vacuum as a greenish-brown liquid, easily soluble in alcohol, ether, and benzene; sp. gr. 0.953. It is neutral to test-paper, and is approximately composed of oleic acid 50 per cent., palmitic acid 36.3, cholesterol 4.12, and glycerol 9.55 per cent. The fat, distilled in a current of steam, yields a small quantity of an ethereal oil, containing ethyl and methyl salts of veratric and hydroxymyristic acids, aldehydes of the lower fatty acids, and high-boiling polyterpenes. The volatile fatty acid described by Pelletier and Caventon could not be detected.

J. T.

Fats of *Amanita pantherina* and *Boletus luridus*. By E. ORTIZ (*Arch. Pharm.*, 229, 290—292).—These fungi yield a considerable amount of fatty oil when extracted with ether. After a short time the oil deposits phytosterol crystals; when freed from these, the fatty material has a thick, oily consistence and a dark-brown colour. Half of the mass consists of free fatty acids. Both fats contained oleic and palmitic acids, glycerol, and phytosterol. J. T.

Proteids of the Oat-kernel. By T. B. OSBORNE (*Amer. Chem. J.*, 13, 327—347).—By concentrating the hot alcoholic extract of freshly-ground oats and treating the residue with alcohol and ether, several fractional precipitates were thrown down containing from 6 to 13·92 per cent. of nitrogen. These fractions, on further treatment, yielded four portions of a coagulated proteid having the mean composition C, 52·96; H, 6·9; N, 16·4; O, 23·74.

A proteid soluble in alcohol was of practically identical composition and contained 2·25 per cent. of sulphur.

The alcoholic extract from oats which had been previously extracted with water yielded an uncoagulated proteid containing C, 53·64; H, 6·88; N, 15·70; S, 1·75.

When 10 per cent. sodium chloride solution was substituted for the water, two portions of uncoagulated proteid were obtained of the composition C, 53·97; H, 6·97; N, 15·66; S, 1·80; O, 21·60.

When the water and salt solution were applied in succession, the uncoagulated proteid extracted by alcohol contained C, 53·63; H, 7·16; N, 15·83; S, 1·74; O, 21·64.

Two distinct proteids can thus be obtained from oats (compare Kreusler, *J. pr. Chem.*, 107, 17). That extracted from untreated oats readily coagulates and becomes insoluble in alcohol, and when wet with absolute alcohol does not absorb moisture from the air; whilst that obtained from oats after treatment with water or salt solution has no tendency to coagulate, is freely soluble in cold alcohol of 0·9 sp. gr., and when wet with absolute alcohol absorbs moisture from the air and becomes gummy. Both substances, when washed with absolute alcohol and dried, are light yellowish powders, soluble in dilute acids and alkalis and reprecipitated on neutralising their solutions. J. W.

Development of Wheat, and Formation of Starch in the Grain. By HÉBERT (*Ann. Agron.*, 17, 97—115).—The author has studied the development of the wheat plant in the light of the recent knowledge obtained as to the composition of straw. Dehérain has shown that much of the undetermined matter in the ordinary analysis of straw consist of vasculose; Wheeler and Tollens, that the saccharifiable substance present in straw is not starch but straw gum, analogous to wood gum, giving by treatment with acids a reducing sugar called xylose; and the author (*Ann. Agron.*, 16, 358) has based on these discoveries a new method for the analysis of straw.

The following table shows the composition of Bordeaux wheat grown at Grignon in 1890, at the different times of sampling:—

Composition of dry matter.	May 13.	June 8	July 2.		July 16. Stems.
			Stems.	Heads.	
Ash	14.95	11.68	9.26	5.93	12.19
Nitrogenous matter (N \times 6.25) ..	21.66	9.81	5.31	9.85	6.72
Fat and chlorophyll	3.50	2.14	1.93	2.61	1.88
Substances soluble in water (ash deducted)—					
Reducing sugars	6.56	4.99	2.89	1.92	2.69
Non-reducing sugars	5.01	6.15	3.64	2.57	3.87
Gums, tannins, &c.	none	0.58	8.53	4.57	7.68
Cellulose	20.18	23.43	26.32	22.93	27.46
Vasculose	9.03	16.39	13.07	13.23	13.73
Straw gum (reckoned as xylose) ..	18.28	26.93	30.51	30.50	25.53
Starch	—	—	—	6.22	—
	99.16	102.15	101.46	100.33	101.74

The ears of grain had by July 16 lost so much by attacks of birds that no analysis was made. The kilograms *per hectare* of the various ingredients contained in the plant at the different dates are given in the next table.

	May 13.	June 8.	July 2.			July 16. Stems.
			Stems.	Heads.	Total.	
Ash	174	553	573	122	695	1260
Nitrogenous substances ..	252	465	328	203	531	695

Straw gum = xylose ..	212	1276	1887	629	2516	2638
Starch	—	—	—	128	128	—

These results throw some light on the source of the starch in the grain. The straw gum, really contained in the stems instead of the starch or amylaceous substance formerly supposed to accumulate there ready for transportation to the grain, does not appear to be the source. It increases in the straw regularly up to the end of maturation, forming 25–35 per cent. of ripe straw, is insoluble in water, difficultly attacked by acids, and requires a long time for transformation into xylose.

To throw more light on the point, analyses were made of different samples of grain (from another district) at different periods of ripen-

ing, viz., July 15 and 23; the detailed analyses are given in the paper. At the earlier period the grain contains about 10 per cent. of reducing sugar. A solution of this sugar heated with phenylhydrazine acetate gave an osazone melting about 210° , which nearly corresponds with the melting point of phenylglucosazone; the sugar should be glucose or levulose, probably glucose. The non-reducing soluble carbohydrate in the grain on July 15 gives the reactions of a dextrin; a search for saccharose gave a negative result. The non-reducing substance in the young stems appears to be dextrin also, so there is reason for supposing that the glucose and dextrin of the early grain are both simply transported from the stems. In the ripe grain no glucose is found, and it is, in all probability, one of the substances transformed into starch. It is certain that the starch is not formed early in the life of the plant and then transported, and it is equally certain that it is not formed by chlorophyll action during the maturation, for at that period the leaves are yellow and withered.

As to the nitrogenous matters, the author's results confirm those of Pierre, which showed an accumulation in the straw and subsequent migration into the grain.

J. M. H. M.

Formation of Phlobaphenes. By A. TSCHIRCH (*Chem. Centr.*, 1891, i, 583; from *Schweiz. Wochenschr. Pharm.*, 29, 62—64).—With few exceptions, the tannins are found dissolved in the cell sap and are oxidised either directly or, in the event of their being present in the form of glucosides, after resolution into their constituents, to red-brown phlobaphenes. To this class of compounds belong quina red, tormentilla red, filix red, ratanlica red, illicium red, nelken red, cinnamon red, kino red, catechu red, &c. The tannins of the oak and sumach (*Rhus coriaria*) as well as the majority of the pathological tannins are either not oxidised at all or but very slowly, and phlobaphenes are not formed. The formation of filix red takes place very slowly, whilst that of quina red is very rapid, and in the case of the tannin in *Cinchona succirubra* the author has observed the change take place at the end of 15 seconds. The behaviour of the tannins when subjected to heat varies greatly, some being very stable whilst others are equally sensitive. In the case of tea, if the leaves are allowed to ferment and are then dried, the phlobaphene is formed and the product is black tea, whilst if the leaves are heated directly after gathering, the tannin is destroyed and the phlobaphene is not formed, the product being green.

J. W. L.

Changes occurring during Ensilage. By O. KELLNER, Y. KOZAI and Y. MORI (*Landw. Versuchs-Stat.*, 39, 105—114).—In continuation of former researches, the authors have further examined the changes which occur in the nitrogenous portion of fodders in silage. It appears that when air is excluded the chemical changes do not result in a loss of nitrogen, and when such silage is dried as for analysis, ammonia is lost by dissociation of its organic salts; as much as 23.3 per cent. of the total nitrogen may thus be lost (buckwheat). When nitrates are present (0.21 per cent. nitrogen in turnip leaves), as much as 10.3 per cent. of the total nitrogen may be lost; this

corresponds with a quantity more than that which is contained in the fodder as nitrate; consequently it appears that under these conditions other nitrogenous matters are destroyed, but hitherto no explanation can be found for this condition of affairs. Drying silage before estimating its digestibility is not advisable; the protoids of rye grass, buckwheat, &c., become less digestible after ensiling. E. W. P.

Analytical Chemistry.

Burette-float for Opaque Liquids. By H. REY (*Ber.*, 24, 2098).—For opaque liquids, the author recommends the employment of a float with two bulbs, so weighted that the upper and smaller one, which bears the usual horizontal mark, is above the surface of the liquid. The readings may then be obtained with as great accuracy as in the case of transparent liquids. H. G. C.

Estimation of Free Hydrochloric Acid in the presence of Acid Phosphates by means of Calcium Carbonate. By C. FRIEDHEIM and H. LEO (*Pflüger's Archiv*, 48, 614—624).—In a fluid such as the contents of the stomach, where free hydrochloric acid and acid phosphates may occur, the acidity may be estimated in the following way:—Free hydrochloric acid is neutralised by shaking the mixture with powdered calcium carbonate in the cold, carbonic anhydride being given off. The acidity of acid phosphates is not altered by this procedure. If the solution is titrated before and after treatment with calcium carbonate, the amount both of the free acid and of the acid phosphates is obtained. This method, previously published (Leo, *Centr. Med. Wiss.*, 1889, No. 26), has been criticised by various observers (Hoffmann, Wagner), and the present paper is chiefly concerned in answering these criticisms. W. D. H.

Detection of Chlorine and of Chlorides in presence of Bromides and Iodides. By G. DREIER (*Bull. Soc. Chim.* [3], 5, 66).—In addition to an aqueous solution of aniline for the detection of chlorine as described in a previous communication (this vol., p. 495), the author recommends a solution of phenol (40 grams) and aniline (5 c.c.) in water (1 litre), which yields a beautiful blue coloration in presence of traces of hypochlorite, the reaction not being affected by the presence of traces of bromine. T. G. N.

Detection and Estimation of Iodine in Urine. By A. F. JOLLES (*Zeit. anal. Chem.*, 30, 288—292).—After the internal or external use of iodine compounds, iodine appears in the urine. To detect it qualitatively, 10 c.c. of the urine should be mixed with an equal volume of concentrated hydrochloric acid, and 2 or 3 drops of weak chlorine water run down the side of the test tube. In presence

of iodine, at the surface of contact a brown ring is formed, which turns blue on adding starch paste. When compounds of the indigo series are produced by the action of the chlorine, they give a similar ring, but one of much less intensity and situated below and separate from the iodine ring. Should the brown ring fail to turn blue with starch, this is probably due to the use of too much chlorine, and a weaker chlorine water should be tried. The test is very sensitive; 1/500 per cent. is about its lower limit.

The method recommended for estimating the iodine is to char the dry residue of the urine, and precipitate the iodine, together with more or less of the chlorine, by silver nitrate. The amount of silver iodide in the weighed precipitate is then ascertained by fusing part of it in a current of chlorine, and calculating from the loss of weight due to the displacement of iodine by chlorine. M. J. S.

Metaphenylenediamine as a Test for Active Oxygen. By P. CAZENÈVE (*J. Pharm.*, 23, 542—544).—The reagent consists of a 1 per cent. solution of the hydrochloride in 93° alcohol, to which 10 drops of ammonia is added. Contact with air, or the passage of a current of oxygen, only causes a slight bluish-green tint after some hours. Oxygen under a pressure of 300 atmospheres does not colour the reagent. On the contrary, when shaken up with platinum black, or animal charcoal, the liquid takes an indigo tint. All the blacks used for decolorising produce the same colour, and the tint varies with the decolorising power. Hydrogen peroxide gives an intense blue tint in the cold, whilst ozonised oxygen produces a reddish-brown coloration. The reagent thus indicates that the active oxygen in the latter case differs dynamically from the preceding cases. J. T.

Belgian Method of Estimating the Soluble Phosphoric Acid of Superphosphates. By D. CRISPO (*Zeit. anal. Chem.*, 30, 301—303).—It was formerly the practice to treat a weighed quantity of the phosphate with a large volume of water at once, and, after digestion with frequent shaking, to estimate the phosphoric acid in solution. By this treatment, however, the phosphoric acid, the monocalcium phosphate, and the iron and aluminium sulphates attack the undecomposed tricalcic phosphate, forming compounds which are not soluble in feebly acid water, and therefore escape estimation. At a meeting of Belgian chemists held two years ago, the following process was therefore adopted as one resembling more closely that which goes on in the soil:—5 grams of the substance is rubbed dry in a mortar, and then treated with a small quantity of water. After thorough disintegration and subsidence, the solution is decanted through a filter into a half-litre flask. This treatment is repeated, the contents of the filter being each time allowed to drain through before refilling. Finally, the residue is rinsed upon the filter and thoroughly washed. Any turbidity produced in the filtrate by the admixture of the various washings is cleared by the addition of nitric acid, before filling up to the mark and estimating by the molybdate method. M. J. S.

Assay of Ferric Hypophosphite. By F. X. MOURK (*Pharm. J. Trans.*, 21, 1177).—0.2 gram of finely-powdered ferric hypophosphite, 1.0 gram of citric acid, and 25 c.c. of water are stirred together until the acid dissolves; then dilute ammonia is added gradually in order to decompose the hypophosphite, the ferric hydrate being largely dissolved by the ammonium citrate. The mixture is frequently stirred for 10 minutes more, then 75 c.c. of a cold, saturated solution of mercuric chloride is added, and after that, hydrochloric acid, drop by drop, with constant stirring, until calomel begins to precipitate. The vessel is allowed to stand in the cold for half an hour, and for a further half hour in a water-bath at 100°. The weight of the mercurous chloride precipitated multiplied by 0.088934 gives the weight of the ferric hypophosphite. R. R.

Bettendorf's Arsenic Reaction. By H. WARNDCKE (*Chem. Centr.*, 1891, i, 760—761; from *Pharm. Zeit.*, 36, 167—168).—In place of the stannous chloride solution in hydrochloric acid, prepared according to the *Pharm. Germ.* III, the author prefers dissolving 1 part of crystallised stannous chloride in 2 parts of strongly fuming, 38—40 per cent., hydrochloric acid.

1 c.c. or 1 gram of the substance to be tested is added to 5 c.c. of the tin solution, the reaction being observed for 15 minutes. Calcium phosphate and zinc oxide dissolve to a colourless solution; 1 gram of bismuth subnitrate causes a pale-yellow coloration, whilst 1 c.c. of *liq. ferri sesquichlorat.* causes a weak, greenish coloration. In most cases, the substance under investigation is heated to boiling with the stannous chloride solution, but in the presence of bismuth subnitrate or ferric chloride, the coloration produced by these substances interferes with the arsenic reaction. J. W. L.

Modification of Pettenkofer's Method of Estimating Carbonic Anhydride in Air. By A. LEBEDINZEFF (*Zeit. anal. Chem.*, 30, 267—279).—The modification consists essentially in protecting the baryta solution completely from contact with unpurified air, or with caoutchouc, at any stage of the work. The baryta store bottle and stopcock burette are connected so as to form a closed system, into which only purified air can enter, and the baryta is measured into thin-walled tubes, of pipette form, previously filled with purified air, which are then sealed before the withdrawal of the burette jet. The air bottle is fitted with a hollow glass stopper, carrying two stopcock tubes. One of the baryta tubes (the total bulk of which must be ascertained) is placed in the dry air bottle before the latter is filled with the air to be analysed. After aspirating through the bottle (which holds 7 to 12 litres) about 200 litres of air, the stopcocks are closed and made air-tight with a mixture of paraffin and wax, the baryta tube is broken, the bottle shaken for half-an-hour, and then left for 24 hours. It is then inverted and connected to a small subsidence bottle (filled with purified air), into which its contents are allowed to flow. The pipette for removing an aliquot portion is inserted through a glass tube, with rubber connector, passing through the caoutchouc stopper, and is then transferred to the titration bottle through a

similar tube. The stopper of the titration bottle carries also the oxalic acid burette and a soda-lime tube. All the apparatus is figured, and the various precautions minutely described. For the standard acid, Trommsdorf's "*acidum oxalicum purissimum*" was crystallised seven times from hydrochloric acid, then from water, and air dried. But although dissolved in the proper proportion to correspond with 1 milligram of CO_2 per c.c., its actual value was found by two independent methods to be only 0.9752 milligram. Phenolphthalein was used as indicator. Special experiments showed that the baryta solution, whether in the store bottle or in the sealed tubes, underwent no alteration during a month. Blank experiments with purified air indicated 0.128 vol. in 10,000 of air. The estimations made up to the present time have only been for the purpose of testing the method. The results obtained in Odessa and its neighbourhood range from 2.88 to 3.34 vols. per 10,000.

M. J. S.

Estimation of Carbonic Anhydride. By F. TSCHAPLOWITZ (*Zeit. anal. Chem.*, 30, 279—282).—The following process is suitable for the estimation of small quantities of carbonates. The substance is decomposed by boiling it with dilute sulphuric acid in the flask *A*, and the carbonic anhydride evolved is absorbed by a measured quantity of potash solution in the vessel *EHG*, which contains glass balls as large as peas. After filling the whole with purified air, there is measured into the bulb *E* 25 c.c. of potash solution of about 1.5 per cent., with enough boiled water to cover the glass balls in *G*. By suction at *a*, whilst *h* is closed, a partial vacuum is produced, and

sulphuric acid is then drawn into *A* from the stopcock funnel. When the absorption of the carbonic anhydride is complete, the balls are

rinsed from *B* and *F* into *G* with hot water, and, after adding excess of barium chloride (0.8 to 1.0 gram), closing, shaking, and leaving for two hours, the residual alkaline hydroxide is titrated in the vessel *G* by means of oxalic acid with turmeric indicator. The strength of the original potash is ascertained by a similar titration, and the difference is the amount neutralised by the carbonic acid. Test analyses show results ranging from 1.4 per cent. deficiency to 0.9 per cent. excess.

M. J. S.

Estimation of Lithium in Mineral Waters. By E. WALLER (*Chem. Centr.*, 1891, i, 641; *J. Amer. Chem. Soc.*, 12, 214—223).—The author has experimented with the methods of Meyer, Gooch, and Carnot for the estimation of lithium.

In converting the alkalis into chlorides, it is to be noted that the barium precipitate (sulphate and carbonate) carries down appreciable quantities of the alkalis, especially lithium, and in order to avoid error the washing must be very thorough, and the barium carbonate should be dissolved and reprecipitated. The liability of lithium chloride to dissociate must also be remembered. In applying Meyer's phosphate method, the chlorides are dissolved in a small and known volume of water, precipitated with excess of disodium phosphate and sodium hydroxide, evaporated to dryness, redissolved in water, an equal volume of concentrated ammonia added, allowed 12 hours to precipitate, and washed with dilute ammonia. Gooch's amyl alcohol method (*Abstr.*, 1887, 528) gives the best results, provided the quantity of chlorides does not amount to more than 0.2 gram. Carnot's fluoride method includes a serious error, the solubility of lithium fluoride being 0.004 gram in 7 c.c. of the ammonia and ammonium fluoride, which is used for washing the precipitate. This washing liquid must be freshly prepared, and any silicon fluoride, which may precipitate, carefully filtered off.

J. W. L.

Estimation of Small Quantities of Silver in Lead Flux. By G. HEPPE (*Chem. Centr.*, 1891, i, 470; from *Chem. tech. Centralans.*, 9, 11).—The author recommends the following method. From 150—200 grams of the finely powdered lead flux is treated at a gentle heat with a saturated solution of lead acetate. The greater part of the lead oxide dissolves, forming basic acetate, the silver remaining undissolved. After allowing to settle, the clear supernatant liquid is decanted, and the residue again treated with lead acetate. The portion remaining insoluble is treated with acetic acid, the solution concentrated, and the silver dissolved out with nitric acid and estimated in the usual manner. A small quantity of copper is almost always present, and frequently a little bismuth.

J. W. L.

Separation of Mercuric Sulphide from Sulphides of the Arsenic and Copper Groups. By K. POLSTORFF and K. BÜLOW (*Arch. Pharm.*, 229, 292—309).—On digesting a mixture of mercury, lead, silver, bismuth, copper, arsenic, and antimony sulphides with a mixture of equal volumes of potassium sulphide and potassium hydroxide solutions, the sulphides of lead, silver, bismuth, and copper are perfectly insoluble, whilst the sulphides of mercury, arsenic, and

antimony are dissolved completely. From this solution the mercury sulphide can be quantitatively separated by warming with ammonium chloride. In the presence of cadmium or tin, the above method is inapplicable. It is convenient to employ a 15 per cent. solution of hydroxide; the sulphide solution is prepared by saturating a measured volume of this solution with hydrogen sulphide, and then adding an equal volume of the hydroxide. The numerical results quoted show the method to be very exact. J. T.

Manganese Ammonium Ferrocyanide. By L. BLUM (*Zeit. anal. Chem.*, 30, 282—283).—On adding potassium ferrocyanide to an ammoniacal solution of a manganous salt in presence of ammonium chloride, the precipitate has the constant composition

Consequently, 1 c.c. of a solution containing 38.487 grams of crystallised potassium ferrocyanide in a litre will precipitate 0.005 gram of manganese. The precipitate is not soluble in acetic acid.

M. J. S.

Volumetric Estimation of Manganese. By L. BLUM (*Zeit. anal. Chem.*, 30, 284—288).—Based upon the facts stated in the foregoing abstract, a method can be founded for the titration of manganese in presence of iron, strictly analogous to that of Donath and Hattensauer for zinc (this vol., p. 113; also *Abstr.*, 1887, 183). The manganese solution is mixed with a little ferric chloride, and a large excess of ammonium chloride, tartaric acid, and ammonia, heated to boiling, and titrated with a ferrocyanide solution, the end of the precipitation being shown by bringing a drop in contact with acetic acid on a porcelain plate, when any excess of ferrocyanide produces a blue colour. In coloured solutions, especially such as from the presence of much iron have a strong yellow colour, the indication is by no means sharp. The process is therefore unsuitable for manganiferous iron, but manganese ores generally give a solution which is sufficiently colourless. The presence of zinc, or of ferrous iron, would cause the results to come out too high. The latter may be peroxidised by nitric acid, and the former is rarely present in manganese ores in noteworthy quantity. The ferrocyanide solution must be standardised with known quantities of manganese, since the commercial salt frequently contains sodium, and therefore precipitates more manganese than would be calculated from the equation. M. J. S.

Separation of Ferric Oxide from Alumina. By F. BELSTEIN and R. LUTHER (*Chem. Centr.*, 1891, i, 809—810; from *Bull. Acad. St. Pétersbourg*, 13, 149—158).—The authors take advantage of the insolubility of basic ferric nitrate in solutions of salts, especially ammonium sulphate, and of the solubility of basic aluminium nitrate in such solutions.

If neutral aluminium nitrate be heated on the water-bath until it ceases to lose weight, water and nitric acid are lost, and the basic nitrate, $2\text{Al}_2\text{O}_3 \cdot 3\text{N}_2\text{O}_5 \cdot 2\text{H}_2\text{O}$, is formed. This nitrate is readily soluble in water, is not decomposed by heating to boiling, and is not precipi-

tated by ammonium sulphate. If the aqueous solution be *boiled* with ammonium sulphate, a precipitate is formed which redissolves, in part, on cooling, and is free from sulphuric acid. If a solution of normal aluminium nitrate be evaporated to dryness on the water-bath with some ammonium nitrate, the formation of the basic nitrate is not interfered with.

Normal ferric nitrate, if heated on the water-bath, loses water and nitric acid with formation of several basic nitrates of varying composition. They vary in colour from yellow to red and brown, and partly dissolve in water to a muddy, dark-red liquid. The solution proceeds more rapidly in hot than in cold water, but the solution is muddier, and passes through a filter still muddy, the solution not becoming clear even if left for several weeks. The iron is present in the colloidal state, and is precipitated by the addition of a few drops of ammonium, sodium, or copper sulphate. Water dissolves the precipitate somewhat, but it is quite insoluble in solutions of salts. It is readily soluble in hydrochloric acid, less soluble in nitric acid, and still less in sulphuric acid. By evaporating normal ferric nitrate with ammonium nitrate, similar basic nitrates are obtained.

For the separation of the two oxides, the solution in nitric acid is evaporated to dryness and heated on the water-bath until acid ceases to be evolved. The residue is treated with hot water, broken up carefully, and boiled for 10 minutes. After cooling, 2—3 c.c. of 10 per cent. ammonium sulphate solution is added, the precipitate allowed to settle, and then filtered. The filtration proceeds slowly through paper, and a layer of fine asbestos on a platinum cone will be found better. The precipitate is washed with cold, and finally with hot, ammonium sulphate solution. The first portions of the filtrate are frequently not quite clear, and it is recommended to pass this through the filter a second time. A little alumina is frequently precipitated with the ferric nitrate, but this may be entirely separated by dissolving the latter in dilute nitric acid and reprecipitating the basic ferric nitrate. The results obtained are satisfactory.

J. W. L.

Decomposition of Chrome Iron Ore by Means of the Electric Current. By E. F. SMITH (*Ber.*, 24, 2182—2185).—The chromium in chrome iron ore can be rapidly and accurately estimated by the following process, which is based on the fact that when an electric current is passed through a fused mixture of potash and chrome iron ore, the chromic oxide is completely converted into potassium chromate.

Caustic potash (30—40 grams) is melted in a nickel crucible placed on a thick copper-wire ring, which is connected with the anode of a battery; the finely divided mineral (0.1—0.5 gram) is carefully added, and then a platinum rod, connected with the cathode of the battery, is introduced into the fused mass through a hole in a watch-glass, placed over the crucible. A current of not more than 1 ampère is then passed for at least 30—40 minutes, but before finally breaking the current, it is reversed for a short time, in order to bring about the oxidation of particles of the mineral which are enclosed in the iron deposited on the cathode. The contents of the crucible are then

digested with water, the solution filtered, the residue washed well with boiling water, and the chromium, which is present in the filtered solution as potassium chromate, estimated either gravimetrically or volumetrically by the usual methods; the portion insoluble in water should be completely soluble in warm hydrochloric acid, otherwise the mineral has not been completely decomposed.

Quantitative experiments gave concordant results, which agreed with those obtained by Dittmar's and by Genth's method for the analysis of chrome iron ore.

F. S. K.

Detection and Estimation of Titanium. By A. NOYES (*Chem. Centr.*, 1891, i, 812; from *J. anal. Chem.*, 5, 39).—0.1 gram of the finely pulverised mineral is fused with 0.2 gram of sodium fluoride and 3 grams of sodium hydrogen sulphate; the flux is treated with 15–20 c.c. of water, filtered, and washed, so that the total volume of liquid does not exceed 30 c.c. The titanium is then determined colorimetrically by comparing the coloration produced by hydrogen dioxide with that obtained with a solution containing a known amount of titanium. The presence of iron interferes somewhat with the determination. The difficulty may be obviated by adding to the standard solution of titanium as much ferric sulphate as will produce the same coloration as the iron in the solution under examination. The strength of coloration produced by the hydrogen peroxide with the titanium may now be measured. If the test is only to be a qualitative one, the solution is divided into two parts and hydrogen dioxide added to one, the yellow colour produced by any titanium being then readily detected.

J. W. L.

Solubility of Thallium Iodide and Estimation of Thallium. By J. H. LONG (*Zeit. anal. Chem.*, 30, 342–344; from *J. anal. Chem.*, 2, 243).—One part of thallium iodide requires for solution 17,000 parts of water at 20°, but when the salt is simply washed with water on a filter, somewhat more water is required. Of 90 per cent. alcohol, 260,000 parts are required: when washing with alcohol on a filter, 1 part dissolved in 500,000. With 50 per cent. alcohol, 1 part dissolved in 37,000 parts on digestion; in 51,000 on washing. In ammonia, whether of 6.5 per cent. or of 2.5 per cent., the same solubility of 1 in 13,000 was found. Ammonia of 1.25 per cent. gave the same solubility as water. In a 10 per cent. solution of potassium iodide, thallium iodide seems quite insoluble, and, even in a weaker solution the solubility is very small. The process recommended for estimation is as follows:—A small excess of potassium iodide is added to the warm concentrated solution of the thallium salt. After complete cooling, the thallium iodide is filtered off by a Gooch filter, washed with 50 per cent. alcohol, and weighed after drying. A correction may be made for the amount dissolved by the alcohol.

M. J. S.

Separation and Estimation of Antimony. By J. THELE (*Annalen*, 263, 361–376).—The method of separating tin and antimony, based on the precipitation of the latter from the solution of the chlorides with metallic iron, is not an exact process; in washing

the precipitated metal, even when the water has been previously boiled, a considerable quantity of antimony passes into solution; the metal also undergoes oxidation to such an extent that, in spite of the loss experienced in washing, the results sometimes come out too high.

Antimony pentasulphide, obtained by precipitating an antimony solution with hydrogen sulphide, and then washing with carbon bisulphide in the usual way, is invariably impure; when antimony is estimated as pentasulphide, the results obtained are too low.

The author has made a number of experiments, the details of which are given, in order to determine the magnitude of the errors in the two methods of estimating antimony just referred to. F. S. K.

Electrolytic Separations. By E. F. SMITH and F. MUEH (*Ber.*, 24, 2175—2181; compare *Amer. Chem. J.*, 12, 252; and *J. Frank. Inst.*, 129, 239; 131, 300).—Gold can be completely deposited from a solution of potassium aurocyanide by means of the electric current; the deposition of palladium, on the other hand, from a solution containing excess of potassium cyanide, does not begin until a current of $\frac{1}{100}$ ampère has been passed for 36 hours. This difference in behaviour can be made use of for the separation of the two metals; employing dilute solutions and a current of suitable strength (0.4 to 1 c.c. of electrolytic gas per minute), the complete separation of the gold requires from 12 to 14 hours, and the deposited metal is free from palladium.

Gold can also be separated from platinum, copper, cobalt, nickel, and zinc in a similar manner; but in the case of zinc, the current strength must be at least 2—3 c.c. of electrolytic gas per minute.

The results of numerous experiments showed that the quantity of gold obtained in this way is, in the majority of cases, in excess of the theoretical, sometimes as much as 0.63 per cent.

When a solution of silver and platinum in excess of potassium cyanide is electrolysed with a current strength equal to 1 c.c. of electrolytic gas per minute, the deposited silver is free from platinum; mercury can be separated from platinum under the same conditions, employing a current equal to 0.2 c.c. of electrolytic gas per minute, but the separation of cadmium and platinum cannot be completely effected. F. S. K.

Action of Hydriodic Acid on Substances containing Sulphur. By R. BENEDIKT and M. BAMBERGER (*Monatsh.*, 12, 1—4).—Zeisel has previously observed (*Abstr.*, 1886, 1079) that the method of estimating methoxyl by boiling the substance with hydriodic acid and determining, as silver iodide, the methyl iodide evolved is not available in the case of some compounds which contain sulphur, because the silver iodide is contaminated with sulphide, and, when an attempt is made to expel hydrogen sulphide, the weight of the silver iodide remaining falls below that required by theory. The authors have experimented with the object of ascertaining whether the presence of sulphur invariably interferes with the estimation of methoxyl by this method. In their investigations, they made use of

Benedikt and Grüssner's apparatus, the bulb of which was filled with a 10 per cent. solution of cadmium iodide and red phosphorus, whereby the hydrogen sulphide was almost entirely retained. The traces of silver sulphide sometimes contained in the precipitate were removed by gentle warming with dilute nitric acid. The following results were obtained:—(1) Potassium methyl sulphate, $\text{KMeSO}_4 + \frac{1}{2}\text{H}_2\text{O}$, gave, on boiling with hydriodic acid, too little methyl iodide and a considerable separation of sulphur. When, to the hydriodic acid, a little red phosphorus was added, a loss of methyl iodide occurred, and this loss seemed to be due to the formation of mercaptan, a substance which, in the form of mercury mercaptide, was found to be unattacked when boiled with hydriodic acid of sp. gr. 1.70. (2) Potassium sulphate was reduced by hydriodic acid to sulphur and hydrogen sulphide, and by hydrogen iodide and red phosphorus to sulphur. (3) Free sulphuric acid was acted on by hydriodic acid in precisely the same way as potassium sulphate. (4) Potassium paraphenolsulphonate gave rise to much sulphur and hydrogen sulphide, and was completely reduced to phenol. (5) The presence of substances containing sulphur, such as potassium sulphate, led to the production of too little methyl iodide when nitroengenol was boiled with hydriodic acid and red phosphorus.

G. T. M.

Estimation of Uric Acid in Urine. By J. B. HAYCRAFT (*Brit. Med. J.*, ii, 1891, 10; *Proc. Roy. Soc. Edin.*, 18, 255—258; and *Zeit. physiol. Chem.*, 15, 436—455).—The author's method of estimating uric acid in urine (*Brit. Med. J.*, ii, 1885) has been adversely criticised by Gossage (*Abstr.*, 1889, 450) and Salkowski (*ibid.*, 1250), and favourably noticed by Herrmann (*Abstr.*, 1888, 1225) and Czapek (*ibid.*). Salkowski alleges that there is no constancy in the amount of silver in silver urate, and quotes twelve analyses which support this view. In the present contribution to the discussion, it is alleged that errors are present in Salkowski's tables, which, when corrected, place his results in accord with those of Haycraft. What they prove is that, by his method, Salkowski finds about 14 milligrams less uric acid than by the silver process. The ratio between the silver and uric acid appears inconstant, because in weak urines a loss of 14 milligrams will be comparatively heavy, whilst in stronger urines the loss will be less felt. This constant difference is due, in part, to imperfections of Salkowski's own method, but the mere existence of the constant difference is stated to prove the proposition that silver urate has a constant composition. This difference has been reduced to within the limits of manipulative error by Herrmann and Czapek.

W. D. H.

Estimation of Ash in Raw Sugar. By A. STIFT (*Chem. Centr.*, 1891. i, 445; from *Öster.-ungar. Zeit. Zuck. Ind.*, 19, 484—489).—Having used von Grobert's method of burning the ash of raw sugars and sugar liquors with the aid of oxalic acid, the author finds that the results obtained coincide with those obtained by burning the ash alone. He finds, however, that the proportion of oxalic acid required is, in most cases, very considerable, from twice the weight of the

sugar in the case of raw sugars to five times the weight of substance in the case of molasses. To use less oxalic acid by sprinkling some more upon parts of the ash which have not burnt perfectly has not proved, in the author's hands, an altogether successful modification.

J. W. L.

Estimation of Sugars with Potassium Cuprocarbonate Solution. By H. OST (*Ber.*, 24, 1634—1636; compare this vol., p. 125).—These determinations were conducted in a manner similar to those already published; the maltose solutions were boiled for 10 minutes before collecting the cuprous oxide; as with other sugars, less attention to details is needed than is required by the use of Fehling's solution. The following table embodies the results:—

Copper.	Maltose hydrate	Maltose, anhydrous.	Copper.	Maltose hydrate.	Maltose, anhydrous.
50	30·6	29·1	180	107·7	102·8
55	33·6	31·9	185	110·8	105·8
60	36·5	34·7	190	114·0	108·8
65	39·4	37·5	195	117·1	111·8
70	41·4	39·8	200	120·3	114·8
75	45·8	43·1	205	123·5	117·8
80	48·8	45·9	210	126·7	120·8
85	51·2	48·6	215	129·9	123·8
90	54·1	51·4	220	133·1	126·4
95	57·0	54·2	225	136·4	129·6
100	59·9	57·0	230	139·8	132·8
105	62·9	59·8	235	143·2	136·0
110	65·8	62·6	240	146·7	139·8
115	68·8	65·4	245	150·2	142·6
120	71·7	68·2	250	153·7	146·0
125	74·6	71·0	255	157·3	149·4
130	77·6	73·8	260	161·0	152·9
135	80·6	76·6	265	164·8	156·6
140	83·6	79·4	270	168·7	160·8
145	86·5	82·2	275	172·7	164·1
150	89·5	85·0	280	176·7	167·9
155	92·5	87·9	285	180·7	171·7
160	95·5	90·7	290	184·9	175·7
165	98·5	93·6	295	189·5	180·0
170	101·5	95·5	298·6	195·0	185·2
175	104·6	99·4			

The factor, Cu/maltose, employed in calculating the above table varies somewhat: it is 1·636 for 25 milligrams of maltose hydrate, 1·676 for 75 milligrams, and 1·531 for 195 milligrams. J. B. T.

Estimation of Milk-sugar. By J. KNOWLES and J. A. WILSON (*Chem. News.*, 63, 191—192).—The authors have compared the estimation of milk-sugar in milk by optical methods with determinations made gravimetrically and volumetrically:—1. By Fehling's solution: Removing casein with acetic acid, precipitating in a neutral solution, and weighing as cupric oxide. 2. By running the diluted milk into

boiling Pavy-Fehling solution. 3. By treating the milk, after the removal of casein by acetic acid, as in method 2. One set of results obtained was as follows:—

Method.	1.	2.	3.	Optical A.	Optical B.
Anhydrous sugar per cent.	4.63	4.71	4.78	5.03	4.92

In optical method A, 70 c.c. of milk is treated with 5 c.c. of basic lead acetate, agitated, diluted to 100 c.c., and the observation taken at 60° in a 200 mm. tube. In method B, 50 c.c. of milk is treated with 2½ c.c. of basic lead acetate and 1 c.c. of mercuric nitrate, agitated, diluted to 57 c.c., and the observation taken in a 220 mm. tube. In both cases, an instrument of the Laurent type was used, and the specific rotation of lactose for the D line was taken as 52.5. The Pavy-Fehling method is regarded as rapid and accurate, but the optical is preferred. When cane-sugar is present in the milk, the amount can be ascertained from the data obtained by noting both the optical activity and the reducing power. D. A. L.

Asbestos Method of Milk Analysis. By F. T. SHUTT (*Chem. News*, 63, 160—161).—Numerous comparative experiments made with the asbestos and other methods of examining milk have led the author to declare in favour of the former method. Milk is weighed into tubes containing asbestos fibre, previously dried in a steam cupboard, then placed in a steam cupboard, through which a strong current of air passes, for 12 or 16 hours, at a temperature between 85° and 90°, and subsequently cooled in a desiccator and weighed. The numbers obtained are 0.34 to 0.49 per cent. lower than those obtained in the ordinary platinum dish method; there is, moreover, no browning of the residue apparent in the asbestos treatment: reasons for these differences are suggested. Fat determinations by various methods did not differ much, but in some experiments slightly higher results were obtained by extracting in Soxhlet tubes and weighing the fat directly than in exhausting the solids in asbestos by means of Stutzer tubes, the increase being attributable to oxidation of the fat, inasmuch as in comparative exhaustions with Soxhlet and Stutzer tubes the latter not only yielded the higher results, but also proved more rapid. Numerous results of analyses are quoted to show that the asbestos method yields concordant numbers. D. A. L.

Apparatus for the Estimation of the Fat in Milk. By E. MOLINARI (*Ber.*, 24, 2204—2209).—Of the numerous methods which have been proposed for estimating the fat in milk, the simplest and the quickest is that of Stokes (*Abstr.*, 1890, 304); although many chemists have testified to the accuracy of Stokes' method, it is nevertheless attended with several sources of error. The author describes a form of apparatus with which, it is claimed, the fat determination in a sample of milk can be accurately carried out by Stokes' process in 30—35 minutes.

This apparatus consists of a flask A, about 90 c.c. in capacity, which is provided with a removable glass cover, and a second flask B,

about 75 c.c. in capacity, to the neck of which is fused a glass cock pierced in three directions. The ground neck of the flask B can be fitted air-tight into that of A so that the whole apparatus is shaped something like a sand glass; one of the apertures in the glass cock on the flask B is connected with a capillary tube passing to the bottom of the flask B, and one with a capillary tube passing to the bottom of the flask A, whilst the third aperture serves to open communication between the air outside and the interior of either of the two flasks; the flask A and its cover are tared once for all.

The analysis is carried out as follows:—The milk (10 c.c.) and concentrated hydrochloric acid (10 c.c.) are placed in the flask A, the mixture carefully heated to boiling, and the boiling continued for not longer than $1\frac{1}{2}$ minutes, the mixture being shaken from time to time; after cooling in water, alcohol-free ether (25 c.c.) is added, the flask B is fitted on to the flask A with the cock closed, and the whole is shaken for a few minutes, the pressure inside and outside being equalised occasionally in the usual manner. The whole apparatus is then inverted and, after 5–6 minutes, the dark-brown acid liquid is drawn off into the flask B, and the cock is closed; the apparatus is now inverted again, the flask A containing the ethereal solution is disconnected, a fresh quantity of ether (10 c.c.) is introduced into the flask B, and the mixture well shaken. The acid liquid is finally drawn off, the ethereal solution in the flask B mixed with that in the flask A, the whole washed two or three times with a little water, the water being drawn off with the aid of the flask B, and the ether evaporated. The fat remaining in the flask A is finally heated at 107° – 110° for at least 10 minutes and twice shaken vigorously to aid the escape of water; after cooling in a desiccator, the flask is weighed until constant. The results agree very well with those obtained by Soxhlet's process, the greatest difference being +0.08 per cent. when the milk is weighed and 0.04 per cent. when the milk is measured.

The apparatus can also be employed in a large number of other qualitative and quantitative analytical processes. F. S. K.

Estimation of Water in Butter. By O. HENZOLD (*Bied. Centr.*, 20, 429; from *Milchzeit.*, 20, 71–72).—20 grams of ignited and cooled (in desiccator) pumice is weighed in a flat dish with a glass rod, into which the butter (10–2 grams) is put. The butter is melted in a drying oven, stirred, and dried for two hours in a water oven. More prolonged drying is not advisable as the butter will increase in weight. The results of several analyses are given in the original paper, showing the method to be trustworthy. N. H. M.

Detection of Margarin in Butter. By R. LÉZÉ (*Compt. rend.*, 112, 813–815).—The attraction of strong syrup for the water contained in butters is utilised to produce practically the same effect as centrifugal separation. 1.5 c.c. of concentrated syrup is placed in a tube provided with a stopper, and having a mark indicating a volume of 10 c.c. The tube is heated in warm water, and butter is added gradually until the total volume of the contents of the tube is 10 c.c.

The tube is then agitated, tightly stoppered, attached to a strong piece of twine, and swung round rapidly for a short time.

Pure butter separates into an upper layer of transparent fat, an intermediate layer of milky emulsion, and a lower layer of syrup. Margarin, on the other hand, shows no clear layer of fat, and the whole remains as an emulsion, with the exception of the lower layer of syrup. This difference makes it possible to detect 15 per cent. of margarin.

Further, butter containing margarin shows, to a greater or less extent, that tendency to remain in superfusion which characterises the fat of margarin, and if tubes of genuine and suspected butter are allowed to cool together, the rate of solidification affords a valuable indication as to purity.

C. H. B.

Examination of Butter and Fats. By J. KÖNIG and F. HARI (*Zeit. anal. Chem.*, 30, 292—300).—The amount of the volatile fatty acids in butter, as found by Reichert's process, is not sufficiently constant to allow of the indirect estimation of butter-fat in margarin with any approach to accuracy. The amount of the soluble barium salts obtainable by saponifying the butter fat by barium hydroxide is far less variable, and at the same time exceeds enormously the proportion yielded by most of the other fats whose presence is at all likely. The process employed is as follows:—5 grams of the fat is dissolved in 60 c.c. of hot alcohol, 40 c.c. of hot baryta water (17·5 grams of barium hydroxide per 100 c.c.) is added, and the whole boiled for 3—3½ hours with reflux condenser. When cold, water is added to 300 c.c., and after mixing and filtering, 250 c.c. is treated with carbonic anhydride until the alkaline reaction has disappeared. It is then evaporated to dryness, redissolved, made up to 250 c.c., and filtered. The barium in 200 c.c. of the filtrate is determined as sulphate, and the amount of barium oxide corresponding with 5 grams of the fat is called its "Baryta number." The following values were found for a variety of fats.

Fat.	Baryta number.	Fat.	Baryta number.

M. J. S.

Estimation of Turpentine in Paints and Varnishes. By H. J. PHILLIPS (*Chem. News*, 63, 275).—Distillation in a current of coal gas is found to be efficient. A T-piece is fitted into the tubulure of a retort, the side tube being connected with the gas supply, whilst the other serves for the thermometer; a tube from the end of the retort passes through one hole in the stopper of a cooled tared receiver, whilst the other hole in the stopper carries a short piece of tubing, from which the coal gas escapes and is ignited; during the distillation, the supply is regulated to sustain a very small flame. In this way the whole of the turpentine is obtained, and, moreover, the residuary products are in a fit condition to be further examined.

D. A. L.

Examination of Chinese Tea. By P. D'YORKOVITCH (*Ber.*, 24, 1945—1955).—The author criticises the methods of Peligot, Mulder, and Zöller for the estimation of theine in tea, and, regarding them as unsatisfactory, has devised the following process, which is said to be both rapid and exact. Ten grams of the finely powdered tea is treated with three successive quantities of 200 c.c. of boiling water, five minutes being allowed for each digestion, and then boiled with two successive quantities of 200 c.c. of water, or more, if necessary, until the last extract is almost, if not quite, free from colour. The extracts are made up to a litre, and extracted thrice with light petroleum to remove oil; &c.; 600 c.c. of the washed solution is then shaken with 100 c.c. of baryta water containing 4 grams of baryta in solution, filtered, and 583 c.c. of the filtrate (corresponding with 5 grams of tea) mixed with 100 c.c. of salt solution (20 grams of salt in 100 c.c. of water), and thrice extracted with chloroform. The extraction is best effected by shaking successive small quantities of the solution with chloroform, since nothing further can be extracted from the solution after the third shaking under these conditions, and not more than 400 grams of chloroform is required. After removal of the chloroform, by distillation to a small bulk and subsequent evaporation in a small dish and drying at 100°, the theine is obtained in perfectly white needles.

In the preparation of black tea the leaves are submitted to a fermentation, which has a most important influence on the quality of the product, and, as Geissler has shown, is carried on at the expense of the tannin. With the object of estimating not only the tannin but also the decomposition products formed from it during the fermentation, or, in other words, determining the extent of the fermentation, the author has improved Lowenthal's method of oxidation with potassium permanganate in the presence of indigo-carmin. The solutions required are the following:—(1.) Decinormal oxalic acid; (2.) a potassium permanganate solution of such a strength (approximately 2.6 grams in the litre) that 130 grams are equivalent to 100 grams of decinormal oxalic acid; (3.) dilute sulphuric acid containing 200 grams of ordinary acid to a litre of water; (4.) baryta-water containing 4 grams of baryta to 100 c.c. of water; and (5.) an indigo-carmin solution prepared by mixing 50 grams of pure indigo-carmin paste with water, adding 50 grams of sulphuric acid and a litre of water, filtering, and diluting until 25 c.c. of the solution

require 20 c.c. of the permanganate for oxidation. The tea solution (10 grams in the litre) is prepared as already described, and of this 40 c.c. is diluted with 500 c.c. of water, treated with 25 c.c. of the indigo-carmin solution and 25 c.c. of dilute sulphuric acid, and titrated with permanganate until the yellow colour becomes evident. The manner in which the permanganate is added is of considerable importance, and the author states that in the titration of the indigo-carmin solution 18 c.c. of the permanganate is added at the rate of 2—3 drops per second, and the remainder at the rate of 1 drop per second, and that in the titration of the tea with indigo-carmin 23 c.c. of the permanganate is run in first of all, then 2—3 drops per second is added, and finally only 1 drop per second until the reaction is completed. If more than 38 c.c. of permanganate is required in the latter titration, a smaller quantity of the tea solution should be taken for the analysis. The amount of the fermentation product is then estimated. For this purpose, 80 c.c. of the tea solution is mixed with 20 c.c. of baryta-water, filtered, and 50 c.c. of the filtrate corresponding with 1/25th of the tea extract is diluted with 500 c.c. water, mixed with 25 c.c. of dilute sulphuric acid, then with 25 c.c. of the indigo-carmin solution, and titrated with permanganate, 18 c.c. of the solution being run in, first of all, then 2—3 drops per second added, and finally 1 drop a second until the reaction is ended. The amount of permanganate employed, less that required for the oxidation of the indigo-carmin, indicates the amount of decomposition products of tannin, or, more correctly, the degree of fermentation which the tea-leaves have undergone. The percentage of tannin and of the fermentation product is calculated by multiplying the weight of oxalic acid equivalent to the number of c.c. of permanganate employed in the oxidation by 31.3, since 63 grams of oxalic acid, according to the author's experiments, correspond with 31.3 grams of tannin, and not with 41.2 grams as stated by Neubauer.

With regard to the comparative values of teas, the author states that the higher the proportion of theine to the total amount of tannin and fermentation products, the more valuable is the tea. The analyses (p. 1303) of teas of the first crop of 1890 are quoted in the paper.

W. P. W.

Quantitative Estimation of Proteids. By L. Devoto (*Zeit. physiol. Chem.*, 15, 465—476).—As all proteids but peptones (and deuteralbumose derived from protalbumose) are precipitated by heat and ammonium sulphate, a method is suggested by means of which the most ordinarily occurring proteids in effusions, blood, urine, &c., may be estimated. In a few cases, however (four cases of pneumonia and one of phthisis with empyema), true peptonuria was observed to occur.

The method consists in precipitating the proteids by saturating with ammonium sulphate and boiling; the reaction of the liquid may be acid, neutral, or alkaline. The precipitate is collected, washed, and weighed in the usual manner.

General and Physical Chemistry.

New Bands and Lines in the Emission Spectrum of the Ammonia-Oxygen Flame. By J. M. EDER (*Monatsh.*, 12, 86—88; compare Magnanini, *Abstr.*, 1890, 97).—By employing the method of spectrophotographic investigation, the author has discovered in the spectrum of the ammonia-oxygen flame some 240 new lines having wave-lengths varying from $\lambda = 5000$ to $\lambda = 2262$ in the extreme ultra-violet.

The emission spectrum of ammonia shows seven very characteristic bands, one of which occurs between the red and the ultra-violet, and the other six, five of which much resemble each other, in the ultra-violet. The wave-lengths corresponding with the most important lines in the different bands have been determined, and are given in this preliminary communication.

G. T. M.

Molecular Refractive Energy of some Triethylsulphine Derivatives. By R. NASINI and T. COSTA (*Gazzetta*, 21, 217—228).—From a determination of the molecular refractive energy of triethylsulphine iodide (*Gazzetta*, 21, 188), the authors recently calculated an exceptionally high value for the molecular refractive energy of the sulphur in these compounds. The following experiments were accordingly made with the iodide, chloride, and hydroxide of triethylsulphine, in order to determine the extent of this variation and the effect of the presence of oxygen in the molecule. The principal results obtained are exhibited in the table on p. 1306, from which it appears that the molecular refractive energy of the iodide remains constant in the same solvent, but varies in different solvents; the value calculated for the sulphur is accordingly very high. The chloride yields similar, but slightly lower, values.

Walter's constants (*Abstr.*, 1890, 202) were also calculated with moderately concordant results. The introduction of oxygen into the molecule occasions a considerable fall in the molecular refractive energy of sulphur, although the type of the compound remains unchanged. The decreasing values given by sulphur in compounds built up on the types of R_2SO , SO_2 , and SO_3 (*Rend. R. Acad. Lincei*, 1885, 1) indicates the existence of some relation which is at present being further investigated.

Strength of Solutions Estimated by their Refraction. By H. O. G. ELLINGER (*J. pr. Chem.* [2], 44, 152—157).—The author uses an Amagat-Jean oleo-refractometer, but prefers to call it a "difference-refractometer." The rays from a stearin candle are passed first through a collimator which has a vertical shutter in place of a slit, movable by a millimetre screw, and then through the solution to be tested, contained in a hollow glass prism which is surrounded by a glass cell with parallel sides, itself surrounded by a similar cell

into which warm water can be placed to raise the temperature. The field of the telescope, which is fixed on the same axis as the collimator, contains a glass scale graduated into 100 parts, 40 on the left, and 60 on the right of the zero. This scale can be moved to the right or left by a fine adjustment. It will be seen that the field is thus divided into light and dark.

The cells are first filled with distilled water and the scale moved until the edge of the dark space corresponds with the zero mark; the solution to be tested is then put into the prism in place of the water, distilled water remaining in the other cells. The solution, having a greater refractive index than the water, will cause the boundary line of the dark space to move to the right or left, according to the position of the prism, to a greater or less extent in proportion to its strength. For instance, a solution of sodium chloride containing 0.01 per cent. shifts the dark space 0.75 division; a solution containing 1 per cent. shifts it 7.5; one containing 2 per cent. shifts it 15. The greatest accuracy is attained by diluting a solution which gives a high deflection.

The author, by using solutions of known strengths, has calculated the "parts per thousand factor" for various salts, that is, the number by which the deflection must be multiplied in order to find the parts of the solid per thousand of the solution. A table of these factors, together with examples of the accuracy attainable, is given. The method is applicable to salts, sugar, dextrin, gum, and alcohol, and is exceedingly rapid.

A. G. B.

Electrical Conductivity of Solid Electrolytes. By J. ROSENTHAL (*Ann. Phys. Chem.* [2], 43, 700—722).—The author has investigated the influence of temperature on the conductivity of electrolytes, using Kohlrausch's method, and making contact with mercury, or (above 100°) with Rose's fusible alloy. He finds that exact quantitative determinations can scarcely be made, on account of the uncertainty involved in imperfect electrical contact of the electrolyte with the metallic part of the circuit, so that his numbers have only a relative value. The conductivity of the substances studied increases as the temperature is raised. Solid lead chromate kept at a constant high temperature exhibits a diminishing conductivity with the time, the rate of diminution being the greater as the temperature is higher.

Lead chloride, bromide, and oxide conduct better at any definite temperature if they have been previously exposed to a higher temperature. Lead chloride, bromide, and iodide are all very plastic below their melting points—a fact which explains, in the author's opinion, why the melting point is not a singular point in the curve of conductivity, as Graetz observed in numerous instances.

The conductivity was found to depend to a great extent also on the state of aggregation of the solid: for example, lead chloride which had been precipitated and compressed had a much greater resistance than the same substance when fused, powdered, and then compressed.

J. W.

Molecular Changes in Metals as shown by their Electrical Conductivity. By H. LE CHAILLIER (*Zeit. physikal. Chem.*, 8, 183—187).—That molecular changes take place abruptly at certain temperatures in certain metals which are being heated has already been shown by Osmond (Abstr., 1887, 14 and 219), these molecular changes being indicated by sudden changes in the physical properties of the metals at the point in question. The author endeavoured to measure the changes in length which accompany these molecular changes, but owing to experimental difficulties could obtain no satisfactory results, except in the case of steel, a sample of which containing 0.9 per cent. of carbon showed a sudden increase in length of 1 mm. per metre at the point of recalescence (730°). Measurements of the electrical conductivity, on the other hand, led to more definite results. Metals which undergo no molecular changes have a conductivity which increases uniformly with the temperature. The same law holds also for the other metals above the temperature at which the last change takes place, for instance, for nickel above 340°, and for iron above 850°. Below these points, the increase in conductivity with the temperature is not uniform, but the temperature coefficient undergoes abrupt changes at certain places.

The point of change of iron, 850°, is not changed by the presence of either large or small quantities of carbon and silicon. Alloys of iron and nickel do not show two points of change each corresponding with that of the metals alone, but have only one point of change, which occurs somewhere between that of nickel, 340°, and that of iron, 850°. This behaviour leads to the conclusion that in these alloys the iron and nickel are not merely mechanically mixed, but have entered into more intimate combination, either in the form of a chemical compound or an isomorphous mixture. Alloys of nickel with copper and zinc behave, on the other hand, as mixtures of these metals, the change not taking place abruptly at any particular temperature, but being distributed over an interval of about 100°. Ferronickel containing 25 per cent. of nickel and 0.8 per cent. of carbon shows in its normal state no point of molecular change above 0°, but when treated with moist hydrogen, which oxidises the carbon, it becomes magnetic, and on heating has a point of change at 550°. On cooling, however, the reverse change only takes place at somewhere between 0° and 100°.

In the course of these experiments, the author had occasion to observe that silver above 600° absorbs hydrogen, this absorption causing a lowering of 30° in the melting point of the metal.

H. C.

Molecular Conductivity of Acids in various Solvents. By K. HARTWIG (*Ann. Phys. Chem.*, 43, 839—840).—The author gives the molecular conductivity and temperature coefficient [α in the formula $k_t = k_0 (1 + \alpha t + \beta t^2)$] of formic, acetic, butyric, and oxalic acids dissolved in methyl, ethyl, and amyl alcohols. As in the case of aqueous solutions, the molecular conductivity usually increases with increasing dilution; but there are exceptions to this rule. For example, formic acid in ethyl and in methyl alcohol, and oxalic acid in ethyl alcohol, show maxima and minima in the curve for molecu-

lar conductivity. When the molecular conductivity is at a maximum, the temperature coefficient is at a minimum, and *vice versa*.

J. W.

Electrochemical Investigations. By F. EXNER (*Monatsh.*, 12, 276—303).—The author has measured the difference in potential between various metals on the one hand and aqueous solutions of the halogens and halogen acids of different concentration on the other; the method employed is identical in principle with that previously described (*Abstr.*, 1889, 456), and the results are given in tables, and in the form of curves.

F. S. K.

Formulæ for Electrolytic Dissociation. By J. D. VAN DER WAAL (*Zeit. physikal. Chem.*, 8, 215—222).—Considering the formulæ for electrolytic dissociation, the author arrives at conclusions similar to those of Arrhenius, that the heat generated by the union of the ions of a salt is either very small or, in some cases, even negative. This result may be explained by assuming that the attraction between the ions and the solvent is very great, greater in some cases, even, than that between the ions themselves.

H. C.

The Nature of Flame. By N. TEGLU (*J. pr. Chem* [2], 44, 246—255).—The author describes the following experiment made with Heumann's "Gas Explosion Apparatus," Fig. 1. When the Woulffe's bottle is filled with illuminating gas by the bent tube, and the latter lighted at *a*, on shutting off the gas and removing the stopper at *b*, air enters, and the flame gradually loses its luminosity,

FIG. 1.

going through a succession of changes; finally, a greenish-coloured cone is formed inside the flame, which diminishes rapidly in size, divides from the outer portion, and passes down the tube as a separate flame until it reaches the bottle, when the mixture of air and gas in it explodes.

A modification (Fig. 2) of the apparatus was then devised. A has a capacity of 1 litre, and is furnished with a tube B, 350 mm. long and 10 mm. in diameter, the tube C serving to pass in the gas. On lighting the gas at *f* and shutting off the supply, the same phenomena are observed as with Heumann's apparatus, and, if air is passed through C at the moment when the flame divides, the separated portion of the latter passes downwards with increased rapidity; when, however, the tube C is pushed up, so that *a* is as near as

FIG. 2.

FIG. 3.

possible to *g*, and gas is passed through it, the flame is again driven upwards; whence it appears that the downward motion of the flame is dependent on the velocity of the combustion, and, since the motion of the gaseous mixture is upward, and, therefore, in the opposite direction to that of the flame, the latter will take up a position corresponding with the resultant of these two motions.

By employing the apparatus shown in Fig. 3, the author has succeeded in bringing the lower flame to a fixed position. A is a tube 600 mm. long and 20 mm. in diameter, and has a funnel, 80 mm. in diameter, attached to it by means of a stopper; C is a tube 3 mm. in diameter, having a bulb *o* sufficiently large to close the funnel when placed in the apex. If *o* is inserted into the funnel, a stream of gas passed up, and, after lighting it at *f*, the tube C be lowered, air will enter with the gas, the flame loses its luminosity, and soon becomes bluish, and, on further lowering C, the flame (as in the experiment first described)

divides. When the gas pressure is constant and the air quite still, the flame which has descended into the tube A can be kept in the same position for any length of time. It is then seen that the cooler upper flame at *f*, which obtains its oxygen from the surrounding air, has its surface turned upwards, whilst that of the lower greenish-coloured and very hot flame is turned downwards. A portion of the gas is therefore burnt in the tube by means of the air mixed with it; whilst the other portion passes upwards and is burnt in the upper flame. By raising C both flames can be made to approach one another, and, when in contact, a flame resembling that of a Bunsen burner results. The Bunsen burner flame, therefore, appears to consist of two conical flames of different heights: in the outer one that part of the gas which escapes burning in the inner flame is burnt at a relatively low temperature by the outside air, whilst in the inner flame, the height of which is conditioned by the velocity of the combustion (see above), the gas is burnt by the air entering from below. When the amount of gas passing into a Bunsen burner is diminished so that the relative quantity of air is increased to such an extent that the flame divides, it burns below. The structure of the Bunsen flame can be shown by holding within it strips of wood 200 mm. long, 100 mm. wide, and 5 mm. thick, charred figures being produced; the burners which give the best indications are those in which the difference in the height of the two flames is large. These figures represent horizontal or longitudinal sections of the flame according to the position in which the strips of wood are held, and they show that in the inner flame the heating surface inclines towards the centre, whilst in the outer flame it inclines outwards.

A. R. L.

Thermochemistry of Organic Chlorine Compounds. By BERTHELOT and MATIGNON (*Compt. rend.*, 112, 1102—1107).—Determinations of the heat of formation and heat of combustion of carbon compounds containing chlorine have hitherto been inaccurate in consequence of the difficulty of converting the chlorine into a definite product. Accurate results can, however, be obtained by exploding the compound in the calorimetric bomb in presence of a solution of arsenious acid. All the chlorine is thus converted into hydrochloric acid, and the arsenious acid remaining is estimated. Carbon chlorides and other compounds rich in the halogen are mixed with camphor before being burned. The following results were obtained:—

	Heat of combustion. Constant volume.	Heat of combustion. Constant pressure.	Heat of formation.
Orthodichlorobenzene (solid)....	676.4 Cal.	676.7 Cal.	+36.7 Cal.
Hexachlorobenzene (solid).....	532.4 "	531.6 "	+63.0 "
Hexachlorethane (solid).....	132.0 "	131.2 "	+36.2 "
Tetrachlorethylene (liquid)	182.3 "	181.8 "	+26.0 "
Carbon tetrachloride (liquid)....	59.3 "	58.8 "	+54.2 "
Chloroform (liquid)	100.15 "	99.95 "	+43.2 "

C_6H_6 gas + $6Cl_2$ = C_6Cl_6 sol. + $6HCl$ gas	develops +205.2 Cal.
C_2H_6 + $6Cl_2$ = C_2Cl_6 sol. + $6HCl$ gas	" +193.0 "
C_2H_4 + $4Cl_2$ = C_2Cl_4 liq. + $4HCl$ gas	" +128.8 "
C_2Cl_4 liq. + Cl_2 = C_2Cl_6 sol.	" +60.0 "
CH_4 + $4Cl_2$ = CCl_4 gas + $4HCl$ gas	" +116.5 "
CH_4 gas + $3Cl_2$ = $CHCl_3$ gas + $3HCl$ gas	" +83.1 "

The substitution of chlorine in the gaseous state develops 30 to 32 Cal. per atom in the paraffin series, and a slightly greater quantity of heat in the benzene series. The addition of chlorine causes almost exactly the same thermal disturbance. C. H. B.

Constitution and Heat of Formation of Bibasic Erythro-oxides. By DE FORCRAND (*Compt. rend.*, 112, 1133—1136) :—

$C_4H_8Na_2O_4$:—Heat of dissolution at 15° +12.49 Cal.; heat of formation (C and Na sol., H and O gas) +307.8 Cal.
$C_4H_8Na_2O_4.4H_2O$:—Heat of dissolution at 15° -2.25 Cal.
$C_4H_8Na_2O_4.2NaOH$:—Heat of dissolution +29.28 Cal.
$C_4H_8Na_2O_4.2NaOH.9\frac{1}{2}H_2O$:—Heat of dissolution +1.79 Cal.

From these results it follows that—

$C_4H_8Na_2O_4$ sol. + $NaOH$ sol. = $C_4H_8Na_2O_4$ sol. + H_2O sol.	develops -0.725 Cal.
$C_4H_8Na_2O_4$ sol. + H_2O liq. = $C_4H_8Na_2O_4$ sol. + $NaOH$ sol.	" +2.155 "
$C_4H_8Na_2O_4$ sol. + $\frac{1}{2}Na_2O$ sol. = $C_4H_8Na_2O_4$ sol. + $\frac{1}{2}H_2O$ sol.	" +16.28 "
$C_4H_8Na_2O_4$ sol. + Na sol. = $C_4H_8Na_2O_4$ sol. + H gas	" +31.165 "
$C_4H_{10}O_4$ sol. + Na_2 sol. = $C_4H_8Na_2O_4$ sol. + H_2 gas.	" +69.305 "
$C_4H_8Na_2O_4$ sol. + $4H_2O$ sol. = $C_4H_8Na_2O_4.4H_2O$ sol.	" +9.02 "
$C_4H_8Na_2O_4$ sol. + $4H_2O$ liq. = $C_4H_8Na_2O_4.4H_2O$ sol.	" +14.74 "
$C_4H_8Na_2O_4$ sol. + $2NaOH$ sol. = $C_4H_8Na_2O_4.2NaOH$ sol.	" +2.93 "
$C_4H_8Na_2O_4.2NaOH$ sol. + $9\frac{1}{2}H_2O$ sol. = $C_4H_8Na_2O_4.2NaOH.9\frac{1}{2}H_2O$ sol.	" +13.91 "
$C_4H_8Na_2O_4.2NaOH$ sol. + $9\frac{1}{2}H_2O$ liq. = $C_4H_8Na_2O_4.2NaOH.9\frac{1}{2}H_2O$ sol.	" +27.49 "

The addition of sodium hydroxide to disodium erythrooxide develops heat, and hence a true compound is formed. The heat of hydration of the erythrooxides is practically constant for the same proportion of water, but is always small; hence the alteration of the hydrates in solution. The thermal disturbances indicate that the compounds have the constitution indicated by the formulæ

given. In all the reactions, the thermal disturbances are about +7 Cal. lower than they would be if $C_4H_{10}O_4$ were substituted for $C_4H_9NaO_4$, and hence the two primary hydroxyl groups have not the same function. C. H. B.

Thermochemistry of Propionic Acid and of the Alkaline Propionates. By G. MASSOL (*Compt. rend.*, 112, 1136—1137.—*Propionic Acid*.—Heat of dissolution +0.62 Cal.; heat of neutralisation by potassium hydroxide in solution +12.95 Cal., by sodium hydroxide +12.49 Cal., these values being practically identical with the corresponding values for acetic and butyric acids.

Potassium propionate forms a white, crystalline mass, which becomes anhydrous at 100°; heat of dissolution +3.02 Cal.; $C_3H_5O_2$ liq. + KOH sol. = $C_3H_5KO_2$ sol. + H_2O sol. develops +24.44 Cal., a number identical with the corresponding number for potassium acetate.

Sodium propionate crystallises with 2 mols. H_2O , becomes anhydrous at 100°, and is very deliquescent; heat of dissolution of the anhydrous salt +3.05 Cal.; $C_3H_5O_2$ liq. + NaOH sol. = $C_3H_5NaO_2$ sol. + H_2O sol. develops +21.27 Cal., the corresponding number for sodium acetate being +27 Cal., and for sodium butyrate +21.7 Cal.

C. H. B.

Heat of Dissolution of Carbon Compounds in various Alcohols. By W. TIMOFÉEFF (*Compt. rend.*, 112, 1137—1139 and 1223—1225). The solubility is expressed (table, p. 1314) in terms of the number of molecules of alcohol required to dissolve 1 mol. of the acid. The heats of dissolution were measured at 12—14°.

In the case of the two bibasic acids, the molecular solubility decreases as the molecular weight of the alcohol increases, whilst the heat of dissolution varies in the contrary direction. In the case of the monobasic acids, the values are all somewhat close, but an increase in the heat of dissolution is accompanied by a decrease in the molecular solubility.

Experiments with the same three alcohols and cadmium iodide, mercuric chloride, naphthalene, and carbamide show that the same law holds good, namely, increased heat of dissolution corresponds with a lower molecular solubility. In the case of methyl alcohol and mercuric chloride, the curve of solubility indicates the formation of a compound. A solution $HgCl_2$ + $25CH_4O$ deposits at 0° crystals of the composition $HgCl_2 \cdot 2CH_4O$, but at 35°, this solution behaves like the others. Carbamide is an exception; the solubility and heat of dissolution in ethyl alcohol are both greater than the corresponding numbers for propyl alcohol.

The ratio of the heat of dissolution of one and the same substance in methyl alcohol to its heat of dissolution in ethyl alcohol is practically identical with the ratio of its heat of dissolution in ethyl alcohol to its heat of dissolution in propyl alcohol. C. H. B.

Thermochemistry of the Camphene Series. By BERTHELOT and MATIGNON (*Compt. rend.*, 112, 1161—1170).—The combustions

	Methyl alcohol.		Ethyl alcohol.		Propyl alcohol.	
	Heat of diss.	Solubility.	Heat of diss.	Solubility.	Heat of diss.	Solubility.
Oxalic acid (anhydrous)	-0.87	—	-1.27	—	-1.88	—
Oxalic acid (hydrated)	-5.21	7.75 at -1°	-5.56	9.05 at -1°	-6.60	15.4 at -1°
"	—	5.95 at 20°	—	7.45 at 20°	—	9.9 at 20°

were made in the calorimetric bomb, the modification previously described being used in the case of the halogen compounds.

	Heat of combustion.		Heat of formation.
	Constant volume.	Constant pressure.	
Terebenthene	+1488·6 Cal.	+1490·8 Cal.	+4·2 liq.
Citrene	+1471·1 "	+1473·3 "	+21·7 "
Camphene hydrochloride	+1467·6 "	+1469·8 "	+64·5 cryst.
Terpylene dihydrochloride.....	+1465·5 "	+1467·7 "	+105·9 "
Terebenthene hydrochloride	+1467·0 "	+1469·2 "	+65·1 "

The heat of combustion of citrene is practically the sum of that of cymene and hydrogen, and hence the union of the two latter to form citrene would develop no heat. It follows that citrene and its isomerides are not cymene hydrides, and do not belong to the benzene series, but are more easily converted into the latter the smaller the thermal disturbance that the change involves.

The heat of formation of citrene is practically identical with that of camphene (22 Cal.), and the conversion of terebenthene into camphene would develop +18·6 Cal. and into citrene +17·5 Cal. This great development of heat does not result from an alteration in molecular weight or in chemical function, but from an increase in the stability of the system.

The formation of camphene hydrochloride from crystallised camphene and gaseous hydrogen chloride develops +21·7 Cal., a value somewhat greater than that for amylene hydrochloride (+17·6). The formation of the terpylene dihydrochloride from liquid citrene, and the gas develops +40·2 Cal., which gives practically the same value for each molecule of hydrogen chloride. The formation of terebenthene hydrochloride under similar conditions develops +38·9 Cal., the thermal disturbance being made up of the heat liberated by the conversion of the terebenthene into the camphene type (418·6 Cal.), and its subsequent combination with hydrogen chloride, the latter change developing +20·3 Cal.

Calorimetric experiments on the direct saturation of these hydrocarbons with hydrogen chloride are very difficult, but the results agree well with those obtained by combustion. The heat of dissolution of citrene dihydrochloride in citrene is -4·65 Cal., and the heat of dissolution of terebenthene hydrochloride in terebenthene is -0·75 Cal. The excess of heat developed by the action of hydrogen chloride on terebenthene is not due to the crystallisation of the product, but to a partial conversion of the terebenthene into a camphene.

C. H. B.

Atomic Weights and the Densities of Liquids. By A. MOULIN (*Compt. rend.*, 112, 1209—1211).—This paper contains a number of

calculations in which the author endeavours to show that "the product of the atomic weight of a liquid substance into its density is the sum of the corresponding products of its elements."

C. H. B.

Study of Evaporation. By O SCHALL and L. KOSSAKOWSKY (*Zeit. physikal. Chem.*, 8, 158—182 and 241—271).—The apparatus employed by the authors is that shown in the figure. The retort *A* holds the liquid under examination, which is heated by the vapour of the same liquid contained in the vessel *B*. The tube *B*, ending in the globe *LL* and worm, serves as a condenser for the vapour of the liquid in *B*, and in this is placed the thermometer which indicates the temperature of the vapour, and consequently also that to which *A* is heated. The tube *C* leads from the retort *A* to the bent tubes 1, 2, 3,

and 4, which form a siphon arrangement to two U-tubes. The short tube *O* connects *C* with the end *G* of the siphon tubes, and serves to establish a uniform pressure in the whole system, and is also used for filling the retort by means of the tap funnel *s*. The condensation of the vapour which passes through the tube *C* is effected by surrounding this with the vessel *M*, which is kept filled with water of a definite temperature, or, if necessary, with a mixture of snow and salt. The tube *G* ends in the Bunsen valve at *V*, which serves to

keep the pressure in the interior of the apparatus constant. When working under reduced pressure, both V and F are connected by means of a T-tube and manometer J with the air-pump, and any

desired pressure can then be obtained. The temperature of the siphon tubes is kept constant by surrounding them with water, and that of the tubes 3 and 4 can be ascertained by means of the thermometer W . Tube 4 is carefully calibrated and divided into millimetres, and the rise of liquid in this tube serves to measure the amount which passes over in a given time from the retort A .

Experiments were made with a large number of organic compounds. The results show that the times required for the evaporation of equal weights of different substances under the same pressure, near the ordinary boiling point and with a constant fall in tension, are inversely proportional to the molecular weights. Only the first members of the alcohol series form exceptions to this rule. The most probable explanation of the above relation is found in the behaviour of the diffusion coefficients, which, when reduced to the above experimental temperatures, pressure (760 mm.), and volume, are found to be proportional to the absolute boiling points under atmospheric pressure.

H. C.

Determination of Molecular Weights by the Boiling Point Method. By E. BECKMANN (*Zeit. physikal. Chem.*, 8, 223—228).—The difficulty in accurately determining the boiling point of a solution increases with the difference of temperature which exists between the heated liquid and the outside air. This may be overcome by surrounding the liquid containing the solution by an outer vessel containing the solvent and kept at the boiling temperature. The inner vessel A , which contains the solution, is of the same form as that used in the freezing point determinations (this vol., p. 784); it is 25 mm. wide, with platinum wire sealed into the bottom and filled to a height of about 35 to 40 mm. with glass beads (*Abstr.*, 1890, 323). This is surrounded by the vessel B , containing about 20 c.c. of the solvent, which is to act as a jacket to A . The two vessels are kept from actual contact by means of the asbestos paper α , and both are connected with reflux condensers K_1 and K . The thermometer used in the determinations is inserted in A , and is similar to that described in the former paper (*loc. cit.*). The chamber C , which is constructed of asbestos cardboard, is heated by means of ordinary Bunsen

burners, and the apparatus itself is protected from the direct action of the flame by the asbestos rings h_1 and h_2 . S, S serve to carry off the products of combustion. Direct heating of the solutions is only

necessary in the case of water, when a small flame, which does not actually come into contact with the vessels A and B, may be used. In all other cases the heat transferred from C is sufficient to raise the solution even in the inner vessel to the boiling point. The outer vessel B may be made of either glass or copper. Experiments with this apparatus are quoted, showing that it gives correct results in molecular weight determinations.

H. C.

Influence of Alkaline Bases on the Solubility of Alkaline Salts. By ENGEL (*Compt. rend.*, 112, 1130—1132) —When sodium hydroxide is added to a solution of sodium chloride saturated at 0° , one equivalent of the hydroxide precipitates half an equivalent of the salt, or 1 mol. of the salt is precipitated for each molecule of the anhydrous oxide, Na_2O , added. At first, the sum of the molecules is a little lower, but afterwards it is a little higher, than would be the case if the law were exactly true. Sodium hydroxide behaves in a similar

manner with solutions of sodium nitrate, and potassium hydroxide precipitates potassium bromide, iodide, or nitrate according to the same approximate law. Ammonia, on the other hand, increases the solubility of ammonium chloride, a result doubtless due to the formation of the double compound described by Troost. C. H. B.

Influence of Potassium Salts on the Solubility of Potassium Chlorate. By C. BLAREZ (*Compt. rend.*, 112, 1213—1215).—Saturated solutions of potassium chlorate, when mixed with solutions of potassium hydroxide or other potassium salts, deposit part of the chlorate. The sum of the quantity of the chlorate remaining in solution and the potassium in the salt added remains constant, this sum being equal to the weight of chlorate that would be dissolved in pure water at the particular temperature. Potassium chlorate, therefore, behaves in the same manner as other potassium salts. C. H. B.

Magnitude of the Pressure in Co-existing Phases of Mixtures, especially in Salt and Acid Solutions. By J. D. VAN DER WAALS (*Zeit. physikal. Chem.*, 8, 188—214).—An application of the results obtained in a former paper (*Abstr.*, 1890, 556) to the case of dilute solutions. The author arrives at the conclusion that it is necessary to assume the occurrence of the dissociation of electrolytes in dilute solutions, but that there is a certain specific attraction between the solvent and dissolved substance which should also be taken into account. H. C.

Change of Colour of Salt Solutions. By D. ISAACHSEN (*Zeit. physikal. Chem.*, 8, 145—149).—According to Wiedemann, the well-known colour change which takes place on heating a solution of cupric chloride is due to the existence of different hydrates at different temperatures, and is accompanied by a change of direction in the curve for the electrical conductivity of the solution. The author has examined a solution containing 13.1 per cent. $\text{CuCl}_2 \cdot 2\text{H}_2\text{O}$, the colour of which changes from blue to green at about 60° . The conductivity was determined for temperatures between 11.6° and 74° . The results, when plotted against the temperatures, give a uniform curve, the conductivity at any temperature being given by $\lambda_t = \lambda_{20} [1 + 0.01841(t - 20) - 0.0000405(t - 20)^2]$. No sudden change of any kind is observed at the point corresponding with the colour change. Similar results were obtained with a solution of cobalt bromide containing 21.8 per cent. CoBr_2 . From this the author concludes that the electrical conductivity of the solution affords no clue to the cause of the colour change.

In order to ascertain whether the dissociation theory affords any explanation of the phenomena, solutions of the above salts were also examined both by the freezing point and vapour pressure methods. The molecular reductions obtained by the two methods were the same in both cases, so that no conclusion is to be arrived at by this means. H. C.

Theory of Double Linkage. By Z. H. SKRAUP (*Monatsh.*, 12, 146—150).—In a double linkage, the two bonds may have either an equal or an unequal value. Against the latter assumption, there is the case of the production of tartaric acid from maleic and fumaric acids, whilst the former is not in keeping with the fact that in additive reactions only one of the bonds of a double linkage is broken. We should have then to assume that the two bonds are at the same time both equal and unequal. This apparent contradiction becomes intelligible if we take into account the internal motion of the atoms within the molecule. In ethane, the two carbon atoms may be regarded as approaching and receding from one another along the line representing their bond of union. In ethylene, on the other hand, the motion of the carbon atoms towards one another may be supposed to take place in the direction of each bond of union alternately, so that as they are approaching one another in the one direction, they are receding from one another in the other. Each bond of union would thus become alternately the stronger and the weaker. Among a large number of molecules, such as those of maleic acid, to each phase in the one direction there will be a corresponding one in the other, so that by the addition of two unlike elements or groups, equal numbers of unlike molecules will result; hence, for instance, the production of inactive malic acid. The motion which is here assumed will depend not only on outside influences, such as that of temperature, but also on the intramolecular, chemical attractions, and in this we have an explanation for the fact that some unsaturated compounds undergo additive change readily and others only with difficulty.

H. C.

Inorganic Chemistry.

Preparation of Hydrobromic Acid. By W. FEIT and K. KUBIERSCHKY (*J. Pharm.* [5], 24, 159—160; from *Pharm. Zeit. Russ.*, 30, 298).—Although concentrated sulphuric acid decomposes potassium bromide with liberation of bromine, when a more dilute acid is used there is no evolution of bromine. To obtain pure hydrobromic acid, 150 c.c. of sulphuric acid of 1.41 sp. gr. is poured on to 100 grams of coarsely-powdered potassium bromide, and the mixture warmed gently and shaken until the salt is dissolved. The liquid is then submitted to distillation; it begins to boil at about 126°, and the temperature slowly rises to 150°, at which point almost the whole of the hydrobromic acid passes over; then the temperature rapidly goes up to 200°, and traces of sulphuric acid are mechanically carried over. The process is now stopped, as between 200° and 250° only small quantities of hydrobromic acid, mixed with a little sulphuric acid, pass over. The distillate is redistilled, collecting only what passes over at 126°; this has a sp. gr. of 1.49, contains 48 per cent. of HBr, is colourless, and contains neither sulphuric acid, sulphurous acid, nor

bromine. 150 grams of bromide yield about 200 grams of acid. If the bromide contains bromate, the receiver is changed when the distillate becomes colourless; the acid thus obtained containing bromine is treated with a little sodium sulphite and rectified with the rest. Gaseous hydrobromic acid may be obtained by distilling the solution containing 48 per cent. from anhydrous calcium bromide.

J. T.

Diammonium Semisulphate, $(\text{N}_2\text{H}_4)_2\text{H}_2\text{SO}_4$. By T. CURTIUS (*J. pr. Chem.* [2], 44, 101—102).—The hydrazine sulphate, $\text{N}_2\text{H}_4\text{H}_2\text{SO}_4$, described in previous communications (Curtius and Jay, *Abstr.* 1889, 340; Curtius and Schulz, this vol., p. 263) is not the normal but the acid sulphate of hydrazine.

Diammonium semisulphate, $(\text{N}_2\text{H}_4)_2\text{H}_2\text{SO}_4$, the normal salt, is obtained when hydrazine hydrate is neutralised with sulphuric acid, and the solution, after concentration, evaporated to dryness in a vacuum. It crystallises in large, glassy, flat, anisotropic prisms, melts at 85° , is extremely deliquescent, has a neutral reaction, and is precipitated from its aqueous solutions as an oil on the addition of alcohol, in which it is insoluble. The addition of a crystal of the salt and rubbing with a glass rod causes the oily sulphate to become crystalline.

W. P. W.

Electrolysis of Fused Compounds of Boron and Silicon. By A. MINET (*Compt. rend.*, 112, 1215—1218).—Sodium chloride (60 parts) is mixed with sodium aluminium fluoride (30 parts), and to this mixture at the moment of fusion is added silica (5 parts) and alumina (5 parts). The mass is kept fused at $700\text{--}1000^\circ$ in an iron crucible, lined with carbon, which serves as the cathode. The anode consists of compressed carbon. The nature of the product depends on the composition of the bath and the strength of the current. Some of the products had the following composition:—

Al	95.5	98.4	97.67	96.80	92.60	89.80	93.40
Si.....	0.33	1.33	1.74	1.60	6.10	8.90	1.00
Fe	0.17	0.63	0.59	1.60	1.30	1.57	6.66

The alloy containing the highest proportion of silicon has a tensile strength greater than that of pure aluminium.

If boric anhydride is substituted for the silica, alloys of aluminium and boron are obtained, in which the proportion of boron may rise to as much as 80 per cent. The alloy is easily separated from the excess of aluminium by the action of sodium hydroxide.

C. H. B.

Sodium and Potassium Nitrite. By H. N. WARREN (*Chem. News*, 63, 294).—A very sensitive surface of spongy platinum is obtained by soaking asbestos yarn in a solution of platinum oxalate, made by heating freshly prepared platonic chloride at 400°F. , until no more chlorine is evolved, then boiling the residue with a slight excess of sodium carbonate, finally dissolving it in oxalic acid, and concentrating the solution. The soaked asbestos yarn, after drying and igniting, is exposed to a current of ammonia and air in a com-

bustion tube, the remote end being heated by a Bunsen to start the reaction; the whole platinised surface soon becomes intensely hot, while dense clouds of ammonium nitrite rapidly form, and are conducted into sodium or potassium hydroxide, where the corresponding nitrite is formed, the evolved ammonia being used for producing a further supply of ammonium nitrite. D. A. L.

Silver Subchloride. By GUNTZ (*Compt. rend.*, 112, 1212—1213).—Silver subchloride or argentous chloride, Ag_2Cl (this vol., p. 983), varies in colour from deep violet-red to violet-black; exposure to sunlight tending to convert it into the latter modification, without loss of chlorine. When heated, it splits up into argentic chloride and metallic silver. It is not attacked by dilute nitric acid, but when warmed with the concentrated acid, it is converted into argentic chloride, mixed with a varying proportion of argentous chloride, forming the coloured products described by Cary Lea (*Abstr.*, 1888, 1). Potassium cyanide decomposes it in accordance with the equation $\text{Ag}_2\text{Cl} + 2\text{KCy} = \text{Ag} + \text{AgCy} + \text{KCl}$, and the heat of formation was determined by means of this reaction. $\text{Ag}_2 + \text{Cl} = \text{Ag}_2\text{Cl}$ develops +29.7 Cal., whilst $\text{Ag} + \text{Cl} = \text{AgCl}$ develops +29.2 Cal., a difference similar to that observed in the case of the two fluorides. $2\text{AgCl} = \text{Ag}_2\text{Cl} + \text{Cl}$ would absorb -28.7 Cal.

C. H. B.

Some Physical Properties of Nickel Carbon Oxide and of other Nickel Compounds. By L. MOND and R. NASINI (*Zeits. physikal. Chem.*, 8, 150—157).—The vapour of nickel carbon oxide burns in the air with a strongly luminous flame, which appears smoky in consequence of the separation of metallic nickel. This flame gives only a somewhat brilliant continuous spectrum. In a Geissler tube, the vapour of the compound gives the spectrum of carbon monoxide only.

The molecular weight of the compound was determined by the cryoscopic method in a benzene solution. The value found was 176.5 instead of 170.6, the theoretical number.

The sp. gr. and coefficients of expansion of the liquid between 0° and 36° were also measured. The sp. gr. at 0° is 1.35613, at 36° 1.27132, the unit being water at 4° . The mean coefficient of cubic expansion between 0° and 36° is 0.001853, which is higher than that of most organic or inorganic compounds. The sp. gr. at the boiling point is 1.25406, and hence the molecular volume is 136.04. The critical temperature calculated from the formula of Thorpe and Rücker is 151° .

The refraction was measured for the hydrogen lines α , β , and γ , and for the lithium, sodium, and thallium lines. The compound is found to have a very strong dispersion, greater when calculated by Ketteler's formula, and slightly less by Gladstone's, than that of carbon bisulphide. The atomic refraction of nickel in this compound is found to be exceedingly high, at least three times greater than that calculated from observations made with other nickel compounds. This fact is in keeping with the view that the valency of

nickel in nickel carbon oxide is greater than in its other compounds, and confirms the opinion derived from the study of the other properties of this substance that in it the nickel behaves as an octad element.

H. C.

Action of Platinic Hydroxide on Tungstates. By A. ROSENHEIM (*Ber.*, 24, 2397—2400).—The author has made the experiments described below to ascertain the course of the reaction between platinic hydroxide and tungstates, and also to throw further light on the nature of the compounds obtained by Gibbs (*Abstr.*, 1877, 847).

Platinic hydroxide is prepared by boiling a solution of platinic chloride in hydrochloric acid with an excess of sodium hydroxide solution, and, after concentrating, neutralising with acetic acid, the precipitate being washed with water containing acetic acid; it generally contains a small quantity of alkali salt. The yield is not a good one, as much of the platinum remains in solution.

When a solution of a pure paratungstate is boiled with platinic hydroxide, according to Gibbs' directions (*loc. cit.*), a large portion of the latter dissolves, forming a deep-red liquid; when the two compounds are heated together in a sealed tube at 250—300°, somewhat more platinic hydroxide is dissolved, and a deep brownish-red liquid is formed, but in neither case could Gibbs' compounds be isolated, the reagents separating out uncombined. As Gibbs does not give analytical data, the nature of his compounds cannot be suggested, but it may be that they consisted of paratungstates containing mechanically occluded platinic hydroxide, coloured by partial reduction. Solutions of metatungstates dissolve platinic hydroxide in considerable quantities on boiling, and still more readily when heated in a sealed tube, although platinic hydroxide is quite insoluble in water, even when heated with it in a sealed tube at 300°; on evaporating these solutions, even under diminished pressure, nothing but the unaltered reagents was obtained. When a concentrated solution of normal sodium tungstate is boiled with platinic hydroxide, the solution becomes faintly yellowish, much less platinic hydroxide being dissolved than in the case of the acid salts; this is opposed to the view that platinic hydroxide acts as an acid. The strongly alkaline solution is filtered as quickly as possible, and, on cooling, a neutral compound, exhibiting the reactions of a paratungstate, separates from the filtrate in small yellow needles of the composition $5\text{Na}_2\text{O}, 7\text{WO}_3, 2\text{PtO}_2 + 35\text{H}_2\text{O}$; this cannot be recrystallised, as it then undergoes decomposition; on this account a further yield is not obtained by concentrating the mother liquor, and the compound cannot be prepared from dilute solutions of sodium metatungstate. It is a double salt of sodium paratungstate (1 mol.) and sodium platinate (2 mols.), as the following experiment proves. When the calculated quantities of sodium paratungstate and platinic hydroxide are boiled with sodium hydroxide solution, the same salt is formed, but this is not the case if sodium hydroxide is excluded.

It appears, therefore, that platinic hydroxide has very weak acidic properties (comparable with those of alumina), which it exhibits only

with such alkaline salts as normal tungstates; it dissolves in para- or meta-tungstates as a base. A. R. L.

Atomic Weight of Bismuth. Composition of Commercial Bismuth and of Commercially Pure Bismuth. By R. SCHNEIDER (*J. pr. Chem.* [2], 44, 23—48).—A controversial paper, in which the author warmly defends Marignac's determination of the atomic weight of bismuth from the criticisms of Classen (this vol., p. 525). Classen, in the same paper (*J. pr. Chem.* [2], 43, 134), states that commercial bismuth contains several units per cent. ("ganze Procente") of copper, iron, and lead, and that purified bismuth procured from various sources also contains considerable quantities ("Procente") of these impurities. To show how misleading are these statements, the author quotes published analyses of commercial bismuth by v. Sill, Barth, and himself, and, in addition, has analysed samples of commercial and of commercially pure bismuth obtained from the smalt works of Saxony, since these furnish about three-fourths of the bismuth annually placed on the market, and may therefore be considered to supply the chief qualities of the metal met with in commerce. Two specimens of commercial bismuth from the smalt works, I, produced prior to October 1, 1890, and II, produced subsequent to that date, gave the following numbers:—

	Bi.	Ag.	Pb.	Cu.	Fe.	As.	S.	Total.
I.	99.791	0.070	0.084	0.027	0.017	—	trace	99.989
II.	99.745	0.066	0.108	0.019	trace	0.011	0.042	99.991

Three samples of bismuth sold as pure were analysed: III, purified from Johannegeorgenstadt metal by precipitation of the basic nitrate and subsequent reduction; IV, purified from Johannegeorgenstadt metal by precipitation of the oxychloride and subsequent reduction; V, purified from smalt works metal by precipitation of the oxychloride and subsequent reduction.

	Bi.	Ag.	Pb.	Cu.	Fe.	As.	Total.
III.	99.922	—	—	0.016	trace	0.025	99.963
IV.	99.849	0.047	0.049	0.019	trace	0.024	99.989
V.	99.892	—	0.065	0.032	trace	trace	99.989

With the object of determining to what extent impurities in bismuth are retained in the acid mother liquor when a nitric acid solution of the metal is precipitated by a known quantity of water, 10 grams of sample I were dissolved in some excess of nitric acid, and the solution stirred into 400 c.c. of water heated to 50°. The precipitate, after washing with distilled water, and drying at the temperature of a water-bath, weighed 6.5 grams; on analysis, the following numbers were obtained:—

	Bi.	Ag.	Pb.	Cu.	Fe.	Total.
VI.	9.9802	0.0070	0.0084	0.0027	0.0017	10.0000
VII.	5.2832	0.0069	0.0081	0.0025	0.0017	5.3024
VIII.	4.6960	—	0.0003(4)	0.0002(4)	—	4.6965
IX.	99.9893	—	0.0064	0.0043	—	100.0000

VI gives the composition of the metal employed, VII that of the solid constituents of the acid liquor, VIII that of the basic nitrate, and IX the percentage composition of the metal obtainable from it by reduction.

W. P. W.

Compounds of Platinic Chloride with Hydrogen Chloride.

By L. PIGEON (*Compt. rend.*, 112, 1218—1220)—Red crystals of chloroplatinic acid, $\text{H}_2\text{PtCl}_6 \cdot 6\text{H}_2\text{O}$, are dissolved in a small quantity of water and mixed with a large excess of concentrated sulphuric acid. A yellow precipitate forms which consists of deliquescent, microscopic crystals, acting strongly on polarised light; they have the composition $\text{H}_2\text{PtCl}_6 \cdot 4\text{H}_2\text{O}$.

If chloroplatinic acid is heated at 100° in a vacuum in presence of fused potash, it melts in its water of crystallisation at about 60° bubbles of gas are evolved, and after two or three days at 100° a solid, crystalline, reddish-brown product remains of the composition $\text{HPtCl}_6 \cdot 2\text{H}_2\text{O}$. When the latter is heated in a vacuum at 200° , in presence of fused potash, it loses the whole of its water and hydrogen chloride, and is converted into anhydrous platinic chloride, but the latter loses no chlorine so long as the temperature is kept below 220° . At 360° , half the chlorine is expelled and platinous chloride is obtained.

The decomposition of chloroplatinic acid would seem to indicate that it is really a hydrochloride of a chloride similar to those described by Engel, thus, $\text{PtCl}_4(\text{HCl} \cdot 2\text{H}_2\text{O})(\text{HCl} \cdot 2\text{H}_2\text{O}) \cdot 2\text{H}_2\text{O}$. It affords a further illustration of the importance of the crystalline hydrate $\text{HCl} \cdot 2\text{H}_2\text{O}$, obtained by Pierre and Puchot.

C. H. B.

Luteorhodium Salts. By S. M. JØRGENSEN (*J. pr. Chem.* [2], 44, 48—62).—When sodium roseorhodium pyrophosphate (Abstr., 1887, 114) is heated in quantities of about 10 grams at 110° for about a week, it becomes yellow and dissolves to a large extent in cold water with a yellow colour. The white, insoluble residue, after dissolution in water acidified with hydrochloric acid and precipitation with dilute nitric acid, gives a white, crystalline compound consisting of a mixture of nitratopurpureorhodium nitrate and luteorhodium nitrate, from which the latter can be separated by a tedious process described at length in the paper. Luteorhodium salts are very stable and can be prepared much more easily by heating chloropurpureorhodium chloride with concentrated aqueous ammonia. When 6 grams of the chloride is heated with 80 c.c. of 25 per cent. aqueous ammonia continuously for 24 hours at 100 — 102° , about 0.6 gram of the chloride remains unattacked and the product consists of 82.5 per cent. of luteo- and 17.5 per cent. of roseo-rhodium chloride; if the heating is continued for four days with quantities of 3—5 grams of the chloride, about 0.01 gram only remains unaltered, and the product consists of luteo-salt almost entirely free from the roseo-salt. The luteorhodium salts, as anticipated (*J. pr. Chem.* [2], 34, 402), show considerable analogy to the roseo-salts, and in no case are differently coloured. As distinguishing characters, the conversion of the roseorhodium chloride, bromide, iodide, or nitrate into purpureo-salts on the one

hand (see Abstr., 1887, 114) and the precipitation of the luteo-salts as the acicular normal orthophosphate on the other may be employed.

Luteorhodium nitrate, $(\text{Rh}, 6\text{NH}_3)_3\text{NO}_3$, on precipitation with dilute nitric acid, is obtained as a snow-white, crystalline powder consisting of small, rhombic prisms and aggregates; when crystallised from hot water, it forms larger crystals showing pyramidal faces, and on the addition of a large excess of concentrated nitric acid to the dilute solution, gives a voluminous precipitate consisting of needles frequently aggregated in six-rayed stars. It is converted into the chloride on repeatedly evaporating it to dryness with hydrochloric acid. One part of the salt dissolves in 48—49 parts of water at the ordinary temperature, and the reactions of the cold saturated solution with a number of reagents are given in the paper.

Luteorhodium chloride, $(\text{Rh}, 6\text{NH}_3)\text{Cl}_3$, crystallises from its hot solution in concentrated hydrochloric acid in anhydrous forms, and may be obtained in rhombic tables, or not infrequently in compact needles, either by adding concentrated hydrochloric acid to its dilute aqueous solution or to that of the nitrate. It crystallises with 1 mol. H_2O in large, efflorescent forms when the neutral, aqueous solution is evaporated over sulphuric acid. It dissolves easily in water, and at 8° requires 7—8 parts for its solution. Digestion with hydrochloric acid for many hours at the temperature of the water-bath does not convert it into the chloropurpureorhodium chloride. The reactions of a 2 per cent. aqueous solution with a number of reagents are described.

Luteorhodium platinochloride, $2(\text{Rh}, 6\text{NH}_3)\text{Cl}_3, 3\text{PtCl}_4, 6\text{H}_2\text{O}$, is obtained when neutral sodium platinochloride is added to a very dilute solution of the luteochloride, and the lustrous, tetragonal prisms which first separate are kept in contact with the mother liquor for some time. It crystallises in orange-yellow, hexagonal forms, is insoluble in water, and when dissolved in warm water containing hydrochloric acid, frequently crystallises from the solution in long needles of the composition $2(\text{Rh}, 6\text{NH}_3)\text{Cl}_3, 2\text{PtCl}_4, \text{H}_2\text{O}$ (dried at 100°), which are isomorphous with the corresponding cobalt and chromium salts; when washed with alcohol and treated with water, it decomposes into luteorhodium chloride and the original platinochloride.

Luteorhodium bromide, $(\text{Rh}, 6\text{NH}_3)\text{Br}_3$, is prepared by adding hydrobromic acid to a solution of the nitrate or chloride. It crystallises in thin, almost regular, hexagonal tables, dissolves easily in water, although less readily than the chloride, and resembles the latter in its reactions.

Luteorhodium sulphate, $(\text{Rh}, 6\text{NH}_3)_2\text{SO}_4, 5\text{H}_2\text{O}$, is obtained when the chloride is decomposed by freshly precipitated silver oxide and water, and the strongly alkaline filtrate containing luteorhodium hydroxide in solution is rendered faintly acid with sulphuric acid, evaporated to one half on a water-bath, mixed with 60 per cent. alcohol until an opalescence is produced, and allowed to remain at the ordinary temperature for about 24 hours. It crystallises in long, colourless, lustrous needles, and dissolves in 43 parts of water at 20° . In its reactions, it resembles the nitrate.

Luteorhodium orthophosphate, $(\text{Rh}, 6\text{NH}_3)\text{PO}_4, 4\text{H}_2\text{O}$.—The 2 per cent.

solutions of the nitrate, chloride, bromide, and sulphate are not precipitated by ordinary sodium phosphate, but on the addition of ammonia an amorphous precipitate of the orthophosphate is obtained, which, in contact with the mother liquor, soon crystallises in long, lustrous needles.

Sodium luteorhodium pyrophosphate, $(\text{Rh}, 6\text{NH}_3)_2(\text{P}_2\text{O}_7)_2\text{Na}_2 \cdot 23\text{H}_2\text{O}$, is obtained as a silky, snow-white, crystalline precipitate on the addition of sodium pyrophosphate to very dilute solutions of the neutral luteorhodium salts. It crystallises in small, hexagonal prisms or rhombic tables, and is almost insoluble in water.

W. P. W.

Acid Luteorhodium and Roseorhodium Nitrates. By S. M. JØRGENSEN (*J. pr. Chem.* [2], 44, 63—66).—*Luteorhodium hydrogen nitrate*, $(\text{Rh}, 6\text{NH}_3)_3\text{NO}_3 \cdot \text{HNO}_3$, is obtained by adding to a solution of 1 gram of luteorhodium nitrate in 100 c.c. of water about 400 c.c. of concentrated nitric acid, filtering through pumice, washing once with concentrated nitric acid, then once with absolute alcohol, and finally drying in a current of dry air during 12—24 hours. It crystallises in long, colourless needles, and, like all the following salts, is decomposed into the normal nitrate by water and dilute alcohol.

Luteocobalt hydrogen nitrate, $(\text{Co}, 6\text{NH}_3)_3\text{NO}_3 \cdot \text{HNO}_3$, prepared in like manner, crystallises in orange-yellow needles, and, like the rhodium salt, does not lose nitric acid when powdered and mixed with absolute alcohol.

Luteochromium hydrogen nitrate, $(\text{Cr}, 6\text{NH}_3)_3\text{NO}_3 \cdot \text{HNO}_3$, like the following compounds, undergoes partial decomposition on treatment with absolute alcohol, and the washing with this reagent is therefore omitted in its preparation. It crystallises in lemon-yellow needles, and cannot be heated at 100° without decomposition.

Roseorhodium hydrogen nitrate, $(\text{Rh}, 5\text{NH}_3, \text{H}_2\text{O})_3\text{NO}_3 \cdot \text{HNO}_3$, crystallises in colourless needles, and on titration by aqueous soda with litmus and with perfectly neutral silver nitrate solution as indicators, gives numbers indicating respectively the presence of one or two molecular proportions of nitric acid, a result due to the basic character of roseo-salts which render litmus blue, although they do not precipitate neutral silver nitrate.

Roseocobalt hydrogen nitrate, $(\text{Co}, 5\text{NH}_3, \text{H}_2\text{O})_3\text{NO}_3 \cdot \text{HNO}_3$, crystallises in needles having the colour of the ordinary roseocobalt salts.

Roseochromium hydrogen nitrate, $(\text{Cr}, 5\text{NH}_3, \text{H}_2\text{O})_3\text{NO}_3 \cdot \text{HNO}_3$, crystallises in needles having perhaps a colour slightly more yellow than that of the normal salts.

W. P. W.

Mineralogical Chemistry.

Agularite, a new Species. By F. A. GENTH (*Amer. J. Sci.*, 41, 401—403).—This interesting mineral was found by Mr. Aguilar, the Superintendent of the San Carlos mine, at Guanajuato, Mexico. The crystals are isometric, being skeleton dodecahedra with only the edges

well developed. The colour is iron-black, fracture hackly, hardness 2·5, and sp. gr. 7·586. Analysis gave results in accord with the formula $\text{Ag}_2\text{S}, \text{Ag}_2\text{Se}$.
B. H. B.

Seleniferous Bismuthinite and Guanajuatite. By F. A. GENIH (*Amer. J. Sci.*, 41, 402—403).—A specimen received by the author as crystallised guanajuatite proves on analysis to be a seleniferous bismuthinite of the composition $4\text{Bi}_2\text{S}_3, \text{Bi}_2\text{Se}_3$. This result suggested a repetition of the analysis of guanajuatite with a specimen that came from an old German collection. The results of the analysis correspond with the formula $\text{Bi}_2\text{S}_3, 2\text{Bi}_2\text{Se}_3$. It is probable that the same mineral has been analysed by Frenzel, and the existence of the species cannot be questioned.
B. H. B.

Griphite, a new Phosphate from Dakota. By W. P. HEADDEN (*Amer. J. Sci.*, 41, 415—417).—The mineral described was found in the Riverton lode, near Harney City. It occurs in the granite in kidney-shaped masses, some of which weigh upwards of 50 lbs. The mineral has a sp. gr. of 3·401 and a hardness of 5·5. Carefully selected material gave on analysis the following results:—

P_2O_5 .	MnO.	CaO.	Al_2O_3 .	FeO.	MgO .	Na_2O .	K_2O .
38·52	29·64	7·47	10·13	4·00	0·15	5·52	0·30
	H_2O .		Cl.	Insol.	Total.		
	4·29		0·11	0·16	100·29		

From these results the author calculates the formula $\text{P}_2\text{R}'_2\text{O}_{10}$, which is a salt corresponding with normal phosphoric acid, and in it $\text{R}' = (\text{Mn}, \text{Ca}, \text{Fe}, \text{H}_2, \text{Na}_2)_{\frac{1}{2}} + \text{Al}_{\frac{1}{2}}$. For this new phosphate the name of griphite is suggested, from $\gamma\rho\iota\phi\omicron\varsigma$ (puzzle) in allusion to its unusual and somewhat enigmatical composition.

The author also describes a phosphate occurring in nodules in the granite of the Nickel Plate tin mine, Dakota. The mineral is dark-green, has a hardness of 5, and a sp. gr. of 3·612. On analysis, it yielded results from which the author calculates the formula $4\text{R}'_3\text{PO}_4 + 9\text{R}'_2\text{P}_2\text{O}_7$, showing that the mineral cannot be regarded as identical with triphylite.
B. H. B.

Alunite and Diaspore from Colorado. By W. CROSS (*Amer. J. Sci.*, 41, 466—475).—The occurrences described by the author lie between the mining towns of Silver Cliff and Rosita, in Custer Co., Colorado, of which district a sketch of the geology is given. The area is regarded by the author as practically a volcano, with two vents in particular, which became true solfataras, and about them the rhyolite has been altered at the one, Democrat Hill, to an alunite rock, and at the other, Mt. Robinson, to an alunite-diaspore rock. In the latter locality, there occurs a rough, finely cellular rock, consisting of bluish quartz and a transparent, colourless mineral in irregular grains. This mineral, at first supposed to be alunite in an unusually pure state, was analysed and found to be diaspore, a result confirmed

by a study of its physical and optical properties. There is but little evidence upon which to base a theory as to the origin of this mineral; but it seems probable that it is here a result of the destruction of alunite.

B. H. B.

Columbite of the Black Hills, Dakota. By W. P. BLAKE (*Amer. J. Sci.*, 41, 403—405).—The specimens of columbite collected by the author in 1884 have been preserved with the intention of preparing a full description as soon as the chemical investigation could be completed. As the numerous analyses published by W. P. Headen (this vol., p. 886) supply this want, the author now gives the results of a crystallographic study of the specimens. Some of the principal measurements for the identification of the faces are given, and for comparison the calculated angles obtained from the axial ratio established by E. S. Dana, $a : b : c = 0.8285 : 1 : 0.88976$.

B. H. B.

Polycrase of North and South Carolina. By W. E. HIDDEN and J. B. MACKINTOSH (*Amer. J. Sci.*, 41, 423—425).—The occurrence and composition of this mineral were recently announced by the authors (*Abstr.*, 1890, 854). Their later attempts in the separation of the metallic acids have given more satisfactory results, as the initial fusion was made with potassium hydrogen sulphate, and not with the sodium salt previously used. The results have enabled the authors to identify the mineral as polycrase, and to deduce for the species the formula

or, if H_2O is grouped under the general head of RO , the simple form $\text{Nb}_2\text{O}_5, 5\text{TiO}_2, 10\text{RO}$.

It is evident that this mineral is not merely an isomorphous mixture of a niobate and a titanate, but that it is a definite salt of a complex inorganic acid, a niobo-titanate. The discovery, by the aid of the spectroscope, of the presence of scandium in this polycrase adds to its interest.

B. H. B.

Axinite, Eudialyte, Titanite, and Monticellite. By F. A. GENTH, S. L. PLNFIELD, and L. V. PIRNEN (*Amer. J. Sci.*, 41, 394—400).—1. *Axinite*.—The authors describe three new varieties of this mineral. The first variety is found as a great rarity at Franklin, New Jersey. The crystals are of a yellow colour, and are of interest, as they have a very unusual habit and possess some rare planes. On analysis, the crystals yielded—

Ignition.	SiO_2 .	B_2O_3 .	Al_2O_3 .	Fe_2O_3 .	CuO .	ZnO .	MnO .
0.76	42.77	5.10	16.73	1.03	0.12	1.48	13.69
		MgO .	CaO .	Total.			
		0.23	18.25	100.16			

The mineral therefore contains a higher percentage of manganese than has ever before been observed.

The second variety described was obtained from Guadalcázar,

Mexico, where it is found in minute crystals associated with white feldspar. The colour is sage-green, and the sp. gr. 3.299. The crystals are tabular, with curved or uneven faces. Analysis gave the following results:—

Ignition.	SiO ₂ .	B ₂ O ₃ .	Al ₂ O ₃ .	Fe ₂ O ₃ .	CuO.	MnO.	MgO.	CaO.	Total.
0.75	42.85	5.17	16.96	5.00	0.19	9.59	0.87	18.49	99.87

The last variety, from McKay's Brook, consists of very small, brown, tabular crystals, arranged so as to form a somewhat columnar, granular rock.

2. *Eudialyte*.—The authors describe crystals of eudialyte from Magnet Cove, Arkansas. The description is in accord with that given by J. F. Williams in 1890.

3. *Titanite*.—One of the rarer minerals of Magnet Cove is titanite. It occurs in small, brown crystals giving on analysis the following results:—

Ignition.	SiO ₂ .	TiO ₂ .	FeO.	MgO.	CaO.	Total.
0.57	30.84	39.35	0.73	trace	28.26	99.75

4. *Monticellite*.—Among the minerals from Magnet Cove, the very rare species monticellite has been discovered. The crystals are characterised by the development of the brachypinacoid and of the brachydome 2P ∞ , and in these respects they differ from those of European localities. On analysis, the mineral yielded results corresponding with the formula (Mg,Mn,Fe)₂SiO₄.Ca₂SiO₄. B. H. B.

Organic Chemistry.

Calculation of the Melting and Boiling Points of Normal Paraffins. By J. HINRICHS (*Compt. rend.*, 112, 1127—1130).—The author shows that the melting and boiling points of the normal paraffins calculated by means of his formula (*Compt. rend.*, 112, 998) agree well with the actual determinations made by Kraft.

C. H. B.

Isomeric Change in Unsaturated Hydrocarbons. By A. FAYORSKY (*J. pr. Chem.* [2], 44, 208—238).—The scheme proposed by the author (*J. pr. Chem.* [2], 37, 382) to explain the isomeric change of mono-substitution derivatives of acetylene into di-substitution derivatives by the action of alcoholic potash finds an exception in the case of allylene. When the latter is treated with alcoholic potash, ethylisopropenyl ether, a compound which does not yield isoallylene under the ordinary conditions, is obtained. The cause of this appeared at first to be that isoallylene is gaseous, and must consequently develop a much higher vapour tension when heated than the liquid derivatives; this tension on reaching a certain limit would prevent the further dissociation of the ether. According to this view,

the ether when heated ought to undergo partial dissociation into isoallylene; this is not the case, however, the compound remaining unaltered when heated in a sealed tube at 100—200° either by itself, or with concentrated alcoholic potash or potassium hydroxide moistened with alcohol. The hypothesis that there is a tendency for the formation of methyl groups is borne out by experiment (see below), whilst the fact that isoallylene could only be formed from ethylisopropenyl ether by the removal of hydrogen from a methyl group explains the stability of the latter.

Isoallylene was prepared by Gustavson and Demianoff's method (Abstr., 1889, 29); it only contained slight traces of allylene, if any. When an alcoholic solution of isoallylene (prepared at 0°) is heated with alcoholic potash in a sealed tube at 160—170° for 12 hours, the residual gas appears to contain more allylene than before the experiment, which is perhaps due to the circumstance that the latter is less easily attacked by the alkali than isoallylene, whilst the same ethylisopropenyl ether is formed as in the case of allylene (see above).

When the so-called diallyl (b. p. 60°), prepared according to Berthelot and Lucas' directions (*Compt. rend.*, 42, 233), is heated in a sealed tube with alcoholic potash for six hours at 170°, and the portion of the product boiling below 85° is again heated with alcoholic potash for the same time at 200°, this being repeated, an isomeric hydrocarbon boiling at 80—85° is obtained, together with a small quantity of a substance boiling at 202°. This hydrocarbon (b. p. 80—85°) is dissolved in twice its volume of dry ether and treated with bromine (2 mols.) at 0°. The mixture is placed in the dark for 24 hours, then poured into a dish, the ether allowed to evaporate, and the liquid portion of the residue removed by treating it with absolute alcohol (see below), the solid portion being crystallised from benzene; it melts at 140—160°. The finely powdered substance is shaken with successive portions of light petroleum, whereby a compound melting at 180° remains, whilst a crystalline product melting at 107° is obtained on evaporating the petroleum. When the above-mentioned alcoholic solution is diluted with water, and the precipitated oil placed over concentrated sulphuric acid, crystals separate after several days; these are freed from the liquid by treatment with 60 per cent. alcohol, crystallised from ether, and identified as diallyl tetrabromide melting at 63°. The 60 per cent. alcohol solution is then evaporated, and the oily residue dried over concentrated sulphuric acid; it decomposes when distilled under a pressure of 30 mm. This liquid and the two above-mentioned solid products are tetrabromides of the composition $C_8H_{10}Br_4$; 80 grams of the diallyl yield 5 grams of the liquid, an equal weight of the compound melting at 180°, and 1 gram of that melting at 107°. When, therefore, diallyl is treated with alcoholic potash, three isomerides are produced whose constitution is uncertain, the more so as observations tend to show that the diallyl itself is not a homogeneous substance (compare Ciamician and Anderlini, Abstr., 1890, 20).

Diisobutenyl, $CH_3 \cdot CMe \cdot CH_2 \cdot CH_2 \cdot CMe \cdot CH_3$, is prepared according to Przibytsek's directions by treating isobutyl chloride with metallic sodium; it boils at 115—116° (783 mm.). When heated at 180° in a

sealed tube, diisobutenyl yields an isomeric hydrocarbon boiling at $134-135^{\circ}$ (768.8 mm.); this solidifies when cooled to 0° , and then melts at 7° . It appears to be identical with Przibyteck's diisocrotyl, $\text{CMe}_2\text{CH}:\text{CH}:\text{CMe}_2$, and the formation of the latter is in harmony with the author's hypothesis that there is a tendency to the formation of methyl groups.

Dipropargyl is prepared according to Henry's directions (Abstr., 1873, 1215). Diallyl tetrabromide (320 grams) is triturated with a large excess of pulverised caustic alkali, and distilled on a sand-bath, whereby a heavy oil (146 grams) is obtained. This, on distillation over calcium chloride, commences to boil at 80° , and the temperature gradually rises to 150° , at which it begins to decompose; the distillation is then continued under a pressure of 40 mm. When the distillate, consisting of the crude mixture of dipropargyl and bromides, is heated on the water-bath in a reflux apparatus for five hours with a large excess of alcoholic potash, and the product fractionated, unaltered dipropargyl passes over at first, whilst Griner's dimethyldiacetylene, $\text{CMe}:\text{C}:\text{C}:\text{CMe}$ (Abstr., 1887, 1033), melting at 65° , is obtained from the portion boiling at $120-140^{\circ}$. The same compound is produced from pure dipropargyl and alcoholic potash, together with a compound of the formula $\text{C}_8\text{H}_{12}\text{O}$.
A. R. L.

Polymeride of Trichloroacetonitrile. By N. TSCHERWEN-IWANOFF (*J. pr. Chem.* [2], 44, 160).—Weddige (Abstr., 1886, 323) showed that trichloroacetonitrile is polymerised by the action of dry hydrogen chloride and prolonged exposure to light. By using hydrogen bromide, the author effected the change in 36 hours, the identity of the polymeride being determined by its melting point (96°) and by analysis.

When Weddige's amidoperchloromethylecyanidine is heated with hydrochloric acid, it yields chloroform, ammonia, and dihydroxyperchloromethylecyanidine, $\text{C}_2\text{N}_2(\text{OH})_2\cdot\text{CCl}_3$ (m. p. $152-153^{\circ}$), and when it is acted on by zinc-dust, it yields amidodimethylecyanidine, $\text{C}_2\text{N}_2\text{Me}_2\cdot\text{NH}_2$, which crystallises in long needles and melts at 170° .
A. G. B.

Oxidation of Sodium Alkyloxides by Atmospheric Oxygen. By F. V. HEMMELMAYR (*Monatsh.*, 12, 151-159).—When sodium methoxide is exposed to dry air at temperatures between 100° and 150° , it is in part oxidised to sodium formate and water; the water thus liberated acts on a further quantity of the methoxide, forming sodium hydroxide and methyl alcohol. Another molecule of the methoxide is oxidised in presence of the sodium hydroxide with the production of water and sodium carbonate.

Sodium ethoxide and sodium amyloxyde behave like sodium methoxide, giving the corresponding fatty acids, that is, acetic and valeric acids respectively. In those cases where the temperature at which the oxidation occurred was raised above 200° , much carbonic acid and traces of oxalic acid and of formic acid were formed. In no case was the quantity of fatty acid produced more than 50 per cent. of that theoretically obtainable from the alkyloxyde.
G. T. M.

Diethylenediamine (Piperazine). By A. LADENBURG (*Ber.*, **24**, 2400—2402).—*Nitrosopiperazine*, $C_4H_8N_2(NO)_2$, is obtained when sodium nitrite is added to a solution of piperazine hydrochloride, and the mixture heated for a short time. The product, when collected and purified by crystallisation from boiling water, forms yellowish, lustrous plates, melts at 158° , and is sparingly soluble in cold water and in ether, readily in boiling water and hot ether. It is not decomposed by boiling sodium hydroxide solution, or by concentrated sulphuric and hydrochloric acids at the ordinary temperature. It gives a deep-blue coloration, after some minutes, with a solution of phenol in concentrated sulphuric acid.

γ -Dimethylpiperazine, $C_4H_8N_2Me_2$, is formed when an aqueous solution of piperazine is heated for several hours in a reflux apparatus with an excess of potassium methyl sulphate, until the mixture is no longer alkaline, and ceases to give the nitroso-reaction. An excess of sodium hydroxide is then added, and the product distilled as long as the base passes over; the distillate is evaporated with hydrochloric acid, and the *hydrochloride*, $C_4H_{14}N_2 \cdot 2HCl$, thus obtained, crystallised from alcohol. It forms lustrous prisms, which lose their lustre at 100° , and develop the odour of the base; it appears also to lose water of crystallisation, and to dissociate at this temperature. The *platinochloride*, $C_4H_{14}N_2 \cdot H_2PtCl_6$, separates from boiling concentrated hydrochloric acid in small, lustrous prisms. The *cadmioiodide*, $C_4H_{14}N_2 \cdot 2HI \cdot CdI_2$, crystallises from boiling water in colourless, thick prisms. The *aurochloride*, the *bismuthiodide*, and the *periodide* are sparingly soluble, crystalline compounds. The *base* is easily volatile, and has a penetrating odour recalling that of methylamine.

A. R. L.

Synthesis of Pyrone. By A. PERATONER and B. STRAZZERI (*Gazzetta*, **21**, 283—312).—I. *Action of Carbon Oxychloride on Copper Oxalacetate*.—It was supposed that these substances would react according to the equation $Cu[CH(COOEt) \cdot CO \cdot COOEt]_2 + COCl_2 = CuCl_2$

$+ O < \begin{smallmatrix} C(COOEt) : C(COOEt) \\ C(COOEt) : C(COOEt) \end{smallmatrix} > CO + H_2O$, yielding an ethyl pyrone-tetracarboxylate, from which pyrone or chelidonic acid might be obtained by hydrolysis. On mixing, however, a benzene solution of carbon oxychloride with copper oxalacetate, and allowing it to remain for about a month, the copper salt takes up an appreciable quantity of chlorine. On treating the product with dilute sulphuric acid, pyruvic acid and a small quantity of a chlorinated derivative of pyruvic acid are formed. The latter compound yields a *hydrazone*, $CH_2Cl \cdot C(COOH) : N_2 \cdot HPh$, which crystallises in short, flattened, yellow needles, melts at 199 — 200° , and dissolves readily in organic solvents and in sodium carbonate, but only very sparingly in water. On heating to 220° , it evolves carbonic anhydride, and the previously fused mass resolidifies. On treating an aqueous solution of the residue with dilute potash, a small quantity of a substance separates, crystallising in small, white, lustrous needles, melting at 110 — 111° . It has feeble basic properties, dissolves in dilute acids and in organic solvents, but only sparingly in water, with which it forms an alkaline

solution. No analysis could be made, but it was ascertained to be free from chlorine.

II. *Formation of Ethyl Dimethylpyronedicarboxylate*.—In order to prepare this, sodium (6 grams) is added to a solution of ethyl acetonedicarboxylate (20 grams) in dry ether (20 c.c.), and heated on the water-bath for two hours. Any unaltered sodium is then withdrawn, dry ether (150 c.c.) added, and dry acetic chloride (12·8 grams) quickly introduced. The action is energetic, and when it is completed the liquid is cooled, shaken with water, and the ethereal solution dried over calcium chloride, and evaporated. The product is ethyl dimethylpyronedicarboxylate, and crystallises from boiling ether in large, colourless, tabular crystals, melts at 79–80°, and is generally identical with the compound prepared by Conrad and Guthzeit (Abstr., 1886, 333), and yields an identical *lutidone* derivative, $\text{NH} < \begin{smallmatrix} \text{CMe}:\text{C}(\text{COOEt}) \\ \text{CMe}:\text{C}(\text{COOEt}) \end{smallmatrix} > \text{CO}$, melting at 220°.

A *disodium derivative* of ethyl acetonedicarboxylate is formed by treating a solution of the ethyl salt (10 grams) in benzene (3 to 4 vols.) with fragments of sodium (4 grams), and heating on the water-bath for 2 to 2½ hours. The reaction is completed when a reddish tinge commences to appear in the solution. The product is a pale-yellow, amorphous powder.

III. *Synthesis of Pyrone and of Chelidonic Acid*.—*Ethyl pyronetetracarboxylate* is formed when ethyloxalic chloride, $\text{COCl} \cdot \text{COOEt}$ (2 mols.), is added to a benzene solution of the sodium derivative of ethyl acetonedicarboxylate just described. When the reaction moderates, the mixture is heated in a reflux apparatus, shaken with water rendered slightly alkaline, and the uppermost layer of liquid dried and freed from the solvent. The product is a deep-yellow oil, which, after a time, deposits minute, acicular crystals of ethyl pyronetetracarboxylate; this melts at 94°, and dissolves readily in alcohol, benzene, acetic acid, and chloroform, but only sparingly in boiling water. It also dissolves in cold alkalis, forming yellow solutions.

Ethyl pyridonetetracarboxylate, $\text{C}_{17}\text{H}_{21}\text{O}_5\text{N}$, prepared by treating the preceding compound with warm, dilute ammonia, crystallises from alcohol in slender, colourless needles, melts at 220°, and dissolves very sparingly in cold water. It is a feeble base, and dissolves in cold, concentrated acids, but is reprecipitated from its solutions on the addition of much water.

When ethyl pyronetetracarboxylate is dissolved in boiling sulphuric acid (1 : 2), the liquid soon turns yellow, and a brisk evolution of carbonic oxide and anhydride takes place, probably owing to a radical decomposition of the compound.

Chelidonic Acid.—Ethyl pyronetetracarboxylate (3 grams) is heated with dilute (1 : 3 by weight) sulphuric acid (100 c.c.), the mixture strongly agitated until solution is complete, then immediately cooled, allowed to remain for 24 hours, and filtered; the solution is now neutralised with barium carbonate, the deposit washed by decantation with cold water, and then thoroughly extracted with boiling water. The extract, on concentration on the water-bath, deposits a small quantity of the sparingly soluble barium chelidonate, and from this

the pure acid may be obtained, by converting it into the silver salt and saponifying. The acid may also be prepared by heating ethyl pyronetetracarboxylate with water (20 parts) and 1 or 2 drops of sulphuric acid for 6—8 hours at 120—130°, and proceeding as before. The yield is 8 per cent. The product has the same properties as the naturally occurring acid. It crystallises in interlaced, colourless needles containing 1 mol. H_2O , which it loses at 110—120°, in a vacuum over sulphuric acid, forms colourless solutions with alkaline carbonates, and yellow ones with the hydroxides; the latter, after boiling for some time, evolve an odour of acetone; it dissolves in boiling water, and very sparingly in the cold. The *silver* salt crystallises in long, colourless needles, sparingly soluble in boiling water. The anhydrous acid melts at 230—235° with evolution of carbonic anhydride. It dissolves in concentrated ammonia, and the solution yields ammonio-chelidonic acid, $C_7H_5O_5N$. The latter yields a dibromo-derivative, $C_7H_3O_5NBr_2 + 2H_2O$, crystallising in colourless needles. Both these compounds give the characteristic reactions of the corresponding derivatives obtained by Lieben and Haitinger (Abstr., 1885, 47, 965) from 2:6-pyronicarboxylic acid.

Pyrone.—Ethyl pyronetetracarboxylate (6 grams) is dissolved in hot, dilute sulphuric acid (1:3), and the solution heated until a slight yellow coloration, accompanied by an incipient evolution of gas, becomes apparent. The solution is then neutralised with barium carbonate, the cold solution filtered, concentrated, and supersaturated with perfectly neutral calcium chloride. The pasty mass is shaken 8 or 10 times with ether; the ethereal solution, on drying, leaves a residue of pyrone in small, colourless crystals, which melt at 30°, and dissolve very readily in water. By treatment with concentrated ammonia it is converted into the pyridone, melting at 147°, identical with that obtained from ammonio-chelidonic acid, and yielding the same dibromo-derivative, $C_7H_3Br_2ON$, as described by Lieben and Haitinger (*loc. cit.*, and Abstr., 1884, 1196; compare this vol., p. 458).

S. B. A. A.

New Derivatives of Stearic Acid. By C. HELL and J. SADOWSKY (*Ber.*, 24, 2388—2396).—The stearic acid employed was prepared from *bassia* oil, which is expressed from the seeds of *Bassia latifolia*, a tree growing in the Himalayas; the oil also contains palmitic and oleic acids.

To obtain pure stearic acid, the oil is saponified with dilute sodium hydroxide, and after precipitating the soap with common salt, it is pressed and dissolved in water; dilute sulphuric acid is now added, and the precipitated fatty acids are repeatedly washed, by fusing under water, until the washings are neutral. The oleic acid is then removed by triturating with cold alcohol, and the residue submitted to fractional distillation under diminished pressure, first at 100 mm., and afterwards at 15 mm.; after three fractionations, the portion passing over between 270° and 290° at 15 mm. is collected separately; it now contains 80 per cent. of stearic acid, and melts at 65°. It is dissolved in an excess of hot alcohol, and on the addition of alcoholic ammonia and a hot alcoholic solution of magnesium acetate, magnesium stearate separates; this is filtered off while hot, washed with

hot alcohol, and, after repeating the operation, dried and decomposed with sulphuric acid (Heintz' method). The acid thus obtained is pure; it crystallises from alcohol in iridescent needles and plates, and melts at 69.2° .

α -Bromostearic acid, $C_{18}H_{35}BrO_2$, is prepared by heating stearic acid (100 grams), well mixed with amorphous phosphorus (washed free from acid with water, and dried at 100° ; 4.5 grams) in a reflux apparatus, and gradually dropping in bromine (dried by shaking with concentrated sulphuric acid; 36 c.c.). The reaction proceeds violently at first, but soon subsides; the heating is continued until bromine vapour is no longer perceptible. The reddish-brown melt is slowly poured into cold water, and washed by decantation until free from acid. It unites with water, forming an opaque mass resembling butter, the quantity taken up being dependent on the temperature; to remove this water it is heated with light petroleum, which dissolves the acid, forming a solution which floats on the water; the solution is separated and put aside, when crystals slowly make their appearance; after two or three recrystallisations, it is obtained as colourless, lustrous needles, or four-sided tables, and melts at 60° . It is insoluble in water, but dissolves readily in the ordinary organic solvents; it has not any irritating action on the skin. The *ethyl salt* is obtained when the acid is gently heated in alcoholic solution and a stream of hydrogen chloride passed through it, the compound separating as an oil; this solidifies on cooling, and after repeated crystallisation from alcohol, forms white, nodular aggregates, melts at $35-36^{\circ}$, and is readily soluble in the ordinary solvents.

α -Hydroxystearic acid, $C_{18}H_{35}O_3$, is formed when the brominated derivative is heated in a reflux apparatus with an excess of alcoholic soda for 24 hours; the sodium salt is collected, washed with alcohol and water, and decomposed with sulphuric acid; the free acid is dissolved in water, and the solution extracted with ether. It separates from a mixture of benzene (1 part) and light petroleum (3 parts) as a white, crystalline powder, melts at $84-85^{\circ}$, resolidifies at $71-70^{\circ}$, and is soluble in the ordinary solvents; 100 parts of alcohol dissolve 0.58 part at 20° . The *silver salt* is a white precipitate, which darkens on exposure to light; the *copper salt* is a green precipitate, whilst the *barium*, *lead*, and *cadmium salts* are white precipitates. The acid is not identical with that described by Fremy, and later by Saytzeff; it differs from this in its solidifying point and in solubility. The constitution of the bromo- and of the hydroxy-stearic acid is proved by the fact that the cyano-acid obtained from the former yields hexadecylmalonic acid on hydrolysis.

α -Amidostearic acid, $C_{18}H_{37}NO_2$, is obtained when the bromo-acid is heated in a sealed tube with an excess of alcoholic ammonia at $135-140^{\circ}$ for 7-8 hours. The crystalline mass is heated on the water-bath to free it from ammonia and alcohol, and washed successively with boiling water, hot alcohol, ether, and dilute sodium hydroxide; it is then crystallised from boiling glacial acetic acid, when it forms a white, crystalline powder which melts at $221-222^{\circ}$; it is insoluble in alcohol, ether, and benzene.

α -Nitridostearic acid, $C_{18}H_{31}NO_2$, is formed when the bromo-acid is

heated with an excess of aniline in an oil-bath at 180—185°. The dark, reddish-brown, partially resinified mass is treated with dilute hydrochloric acid to remove the aniline, and washed with water and a little alcohol; it is then purified by repeated fractional precipitation from its solution in boiling glacial acetic acid, and final crystallisation from alcohol. It forms a white, granular powder, melts at 84·5°, and is readily soluble in benzene, ether, and alcohol, but only sparingly in light petroleum.

A. R. L.

Action of Bibasic Acid Chlorides on Ethyl Sodicyanacetate. By P. T. MULLER (*Compt. rend.*, 112, 1139—1141).—Succinic chloride (1 mol.) and ethyl sodicyanacetate (2 mols.) react in presence of dry ether, yielding *ethyl succinocyanacetate*, a white compound soluble in chloroform in the cold. After crystallisation from chloroform, it melts at 125—126°. It has the composition

Phthalic chloride yields *ethyl phthalocyanacetate*,

a product insoluble in ether and in water, but soluble in benzene or chloroform, from which it separates in white crystals melting at 175°, with decomposition. When these compounds are boiled with water, they yield ethyl cyanacetate and succinic acid or phthalic acid respectively. Prolonged ebullition with water splits up the ethyl cyanacetate into carbonic anhydride and ammonium acetate, probably with intermediate formation of acetonitrile.

The products obtained from the bibasic acid chlorides do not react with water in the same way as the products obtained by Haller from the monobasic acid chlorides.

C. H. B.

Levulinic Acid: Acetonediacetic Acid Dilactone. By A. MICHAEL (*J. pr. Chem.* [2], 44, 113—129).—According to Kent and Tollens (*Annalen*, 227, 229), levulinic acid distils in a vacuum at 157—160°; but the acid prepared by the author distilled at 148—149° at 15 mm.

Ethyl levulinate was prepared in three different ways, namely, by the action of hydrogen chloride on the acid dissolved in alcohol (Abstr., 1881, 410), by heating silver levulinate with ethyl iodide in a sealed tube at 100° for 15 hours, and by heating levulinic acid with alcohol and sulphuric acid; in each case the ethyl salt obtained was an oil, soluble in water, and boiling at 203—204° (compare *loc. cit.*, and Conrad, who prepared the salt by the last-mentioned method, and states that it is insoluble in water; Abstr., 1878, 137).

Ethyl levulinate hydrazone was obtained by Fischer's method, namely, the action of phenylhydrazine on the ethereal salt (Abstr., 1887, 149); it crystallises in plates or prisms, begins to soften at 103°, and melts at 106—108° (not 110°). Water is separated during its formation, not alcohol. Fischer (*loc. cit.*) has pointed out that α -ketonic acids will form hydrazones in the presence of mineral acids;

and although ethyl levulinate behaves as an α -ketonic acid derivative in this respect, levulinic acid does not, no hydrazone being formed.

The *oxime* $C_7O_3H_{13}N$, obtained by the action of hydroxylamine on ethyl levulinate, crystallises from light petroleum in large, colourless, obliquely truncated, prismatic needles, melts at $38-39^\circ$, and is sparingly soluble. This compound should be identical with that obtained by Müller (Abstr., 1883, 1129) by the action of ethyl iodide on silver γ -isonitrosovalerate, but Müller's ethyl derivative is an oil which does not solidify; the author repeated Müller's experiment, and obtained an oil half of which distilled between 135° and 160° under a pressure of 40 mm., and the other half between 160° and 164° . An analysis of the latter half led the author to conclude that it contained the crystalline oxime, but was too impure to crystallise.

The *oxime* $C_7H_{10}N_2O_4$, obtained by the action of hydroxylamine on acetonediacetic acid dilactone (Abstr., 1890, 30), crystallises with 2 mols. H_2O in large, lustrous, colourless, pointed prisms; it blackens at 240° , decomposes at $248-250^\circ$, and dissolves sparingly in cold, more easily in hot, water and alcohol. The aqueous solution is feebly acid, but does not evolve carbonic anhydride from sodium carbonate.

Bredt's hydrazone (Abstr., 1890, 864) is also obtained when the dilactone reacts with phenylhydrazine hydrochloride in aqueous solution; it begins to melt at 290° , and melts completely at $298-301^\circ$, with discoloration. When the dilactone and phenylhydrazine hydrochloride react in presence of sodium acetate, a compound which crystallises in prismatic plates is formed; this softens at $130-135^\circ$, solidifies again at a higher temperature, and decomposes at about 230° .

The author discusses the probable constitution of ethyl levulinate and acetonediacetic acid dilactone dioxime in the light of the above reactions, and concludes his paper by a seriatim refutation of Bredt's reasons for considering levulinic acid to be a γ -hydroxylactone (*Annalen*, 253, 314; 256, 314; Abstr., 1890, 863). Our present knowledge of the subject is in favour of the ketonic constitution for levulinic acid.
A. G. B.

Action of Zinc on Ethyl Dibromosuccinate. By A. CLAUS (*J. pr. Chem.* [2], 44, 110—112).—A reply to Michael and Schulthess (this vol., p. 1184) on the question as to whether an intermediate compound of zinc with the elements of ethyl dibromosuccinate is formed prior to the decomposition into zinc bromide and ethyl fumarate.
W. P. W.

Conversion of Maleic Acid into Fumaric Acid. By Z. H. SKRAUP (*Monatsh.*, 12, 107—145; compare Abstr., 1890, 1397).—At a temperature of 100° , and under the ordinary pressure, water does not convert maleic into fumaric acid; but at a higher temperature, and under increased pressure, the change takes place, the amount of fumaric acid produced varying considerably with the conditions, although in no case is the conversion complete (compare Tanatar, *Chem. Centr.*, 1891, 17). At low temperatures, part of the maleic

acid remains unchanged, whilst at higher temperatures it is to a large extent converted into a malic acid, which is most probably identical with the inactive variety obtained by Loydl from fumaric acid and sodium hydroxide solution. The same inactive variety of malic acid is obtained on heating an aqueous solution of fumaric acid at 180—190°.

Concentrated hydrochloric acid converts maleic acid at ordinary temperatures into a mixture of fumaric acid and chlorosuccinic acid, but the latter is not formed by the action of hydrochloric acid on fumaric acid. Hydriodic acid rapidly converts maleic into fumaric acid, probably with the production of some succinic acid. Benzenesulphonic acid, like sulphuric acid, is almost without action on maleic acid under ordinary conditions; whilst oxalic acid at a high temperature induces conversion into malic acid, the oxalic acid itself undergoing decomposition, with formation of formic acid and carbonic anhydride. Heated in sealed tubes with benzenesulphonic acid, or with sulphuric acid, maleic acid in aqueous solution is only very slowly converted into fumaric acid, the presence of these acids appearing to hinder the change. Organic acids, such as formic, acetic, butyric, and isobutyric, have very little influence on the conversion of maleic acid.

The copper, lead, and silver salts of maleic acid are partly converted into fumaric acid on treatment with hydrogen sulphide, the copper and lead salts giving the largest yields. Hydrogen sulphide alone has little effect on maleic acid, but when an aqueous solution of the acid is saturated with hydrogen sulphide and sulphurous anhydride and then warmed, a very considerable yield of fumaric acid is obtained.

The author gives numerous details of his work, and in conclusion supports the view that the conversion of maleic into fumaric acid is a purely catalytic action, and is quite independent of the presence or absence of water during the change (compare Anschütz, *Abstr.*, 1890, 363). G. T. M.

Methylene Derivatives of Carbamide and of Thiocarbamide.
By F. v. HEMMELMAYR (*Monatsh.*, 12, 89—97).—*Methylenethiocarb-*

amide, $\text{CS} \begin{smallmatrix} \text{NH} \\ \diagup \quad \diagdown \\ \text{NH} \end{smallmatrix} \text{CH}_2$, or, according to the investigations of Storch,

$\text{NH}:\text{C} \begin{smallmatrix} \text{S} \\ \diagup \quad \diagdown \\ \text{NH} \end{smallmatrix} \text{CH}_2$, is obtained on mixing together equal weights of thiocarbamide and the so-called chloromethyl alcohol of Lösekann (*Chem. Zeit.*, 14, 1408—1409). Much heat is developed during the reaction, and hydrogen chloride escapes. The product, which solidifies on cooling, is freed from methyl alcohol, dissolved in water, and the solution gently warmed, when the compound is precipitated in the form of white, insoluble flocks. It is almost insoluble in all ordinary solvents, 1 part requiring 50,000 parts of water and 8,000 of alcohol for its solution at ordinary temperatures. When warmed with mineral acids and with bases, it dissolves, forming thiocarbamide and formaldehyde. Nitric acid, potassium permanganate, and bromine water oxidise the sulphur of the compound to sulphuric acid. On long-

continued boiling with water, methylenethiocarbamide is resolved into thiocarbamide and formaldehyde. It commences to decompose at 180° with evolution of ammonia, and at 200° melts, forming a brown liquid; in its chemical and physical properties it closely resembles ethylenethiocarbamide (compare Reynolds, *Krit. Zeitschr.*, 1871, 325).

Methylenecarbamide, $\text{CO} \begin{smallmatrix} \text{NH} \\ \text{NH} \end{smallmatrix} \text{CH}_2$, is prepared by warming a mixture of equal weights of carbamide and chloromethyl alcohol, and treating the product in a manner similar to that indicated in the preparation of the corresponding thiocarbamide, to which the new compound shows a considerable resemblance, both in appearance and properties. It begins to decompose at 200°, with evolution of ammonia, and at 240° melts to a brown liquid, which solidifies on cooling, and is soluble in hot water. Mineral acids resolve it into carbamide and formaldehyde, and the same change is produced by long-continued boiling with water. G. T. M.

Formation of Uric Acid and of Xanthine Bases, and the Production of Leucocytosis in Mammals. By J. HORBACZEWSKI (*Monatsh.*, 12, 221—275).—It has been previously shown (Abstr., 1890, 184) that uric acid is produced when an extract of the spleen is warmed for some hours with fresh arterial blood or with a dilute solution of hydrogen dioxide, or exposed to the air at a moderate temperature. The extract used in the experiments was prepared by digesting the fresh spleen with distilled water at 50° for eight hours; during this process putrefaction sets in, and a moderate gas evolution commences. The filtered extract is then carefully precipitated with lead acetate, allowed to settle, and the clear solution filtered. The extract obtained in this way contains substances which are decomposed on boiling in absence of oxygen with formation of xanthine and hypoxanthine; if, however, decomposition takes place in presence of oxygen, a quantity of uric acid, equivalent to that of the xanthine bases, is produced. Experiments showed that these mother substances are present in the lymphatic elements of the spleen, especially in the nuclei, as has been suggested previously by Kossel, Schröder, and others.

An examination of a number of organs, obtained chiefly from young calves, but in some cases from fresh corpses, showed that they all, except the sinews, give uric acid when treated with fresh blood until putrefaction sets in; with the exception of calves' brain and calves' lungs, which in one case each gave moderately large quantities of uric acid, neither the blood nor any of the organs contains any appreciable quantity of this acid before the treatment.

When a dilute alkaline solution of nucleïn, prepared from the spleen as described by Miescher, is injected subcutaneously into a rabbit, the quantity of uric acid in the urine is increased; the same result is observed when nucleïn, suspended in water, is introduced into the human system.

The increase in the number of leucocytes in the blood of man, on taking mixed animal and vegetable food after a fast of 18 hours, is

accompanied by an increased secretion of uric acid, but the total quantity of nitrogen excreted in the urine is not very materially augmented. When vegetable food only is taken after a fast of 18 hours, the results vary greatly with different individuals; in some cases the quantity of uric acid excreted is doubled, in others a hardly perceptible increase takes place.

Various experiments showed the close relationship between the number of leucocytes in the blood and the quantity of uric acid secreted in the urine; it seems probable that in mammals, under normal conditions, the uric acid is formed from the decomposition products of the leucocytes.

Quinine and atropine, given in small doses to man after an 18 hours fast, cause a diminution in the number of leucocytes in the blood, and also lessen the secretion of uric acid; small doses of pilocarpin, given under the same conditions, increase the number of leucocytes, and in some cases the quantity of uric acid secreted is also increased; antipyrine and antifebrine increase the number of leucocytes, but diminish the uric acid secretion.

Nuclein from spleen, and probably also other nucleins, produce, compared with albumin, a relatively very intense leucocytosis; in the case of a man who had fasted for 18 hours, a dose of 5 grams of nuclein increased the number of leucocytes 83 per cent.; in two other experiments with different individuals the increase was 53.1 and 60.5 per cent. respectively. This result is probably due to a proliferation of the lymphoid elements in the lymphoid tissues of the intestinal canal and mesenteric and lymphatic glands, as well as in the spleen, marrow, &c. F. S. K.

Azines of the Uric Acid Group. By O. KÜHLING (*Ber.*, 24, 2363—2369).—Hinsberg (*Abstr.*, 1885, 909) obtained hydroxycarboxytoluquinoxaline ureide by mixing aqueous solutions of 3:4-diamidotoluene and alloxan; the author has succeeded in preparing alloxazine and certain of its derivatives by employing the hydrochloride of the orthodiamine instead of the free base, under the conditions described below.

Alloxazine, $C_8H_4 \begin{smallmatrix} N:C \cdot NH \cdot CO \\ N:C \cdot CO \cdot NH \end{smallmatrix}$ is formed when aqueous or alco-

holic solutions containing equivalent quantities of alloxan and 1:2-diamidobenzene hydrochloride are mixed and heated for a short time; the liquid becomes yellow, and a thick, yellow precipitate separates, which is collected and repeatedly boiled with water; it consists of microscopic needles. The compound is insoluble in water and in ether and very sparingly soluble in alcohol; it dissolves in alkali carbonates and is reprecipitated on the addition of a mineral acid; it decomposes above 300°. The alkali salts are readily soluble in water and are partially decomposed by carbonic acid; the *barium salt* is a flocculent precipitate which could not be obtained of constant composition. The *azine* is not completely converted into the corresponding hydroxyquinoxalinecarboxylic acid when heated with an excess of aqueous potassium hydroxide for nine hours, thus differing from Hinsberg's ureide (*loc. cit.*).

Tolualloxazine, $C_8H_3Me \begin{smallmatrix} N:C \cdot NH \cdot CO \\ | \\ N:C \cdot CO \cdot NH \end{smallmatrix}$, is obtained from alloxan and 3:4-diamidotoluene hydrochloride in a similar manner to the last-described compound, which it closely resembles.

Naphthalloxazine, $C_{10}H_5 \begin{smallmatrix} N:C \cdot NH \cdot CO \\ | \\ N:C \cdot CO \cdot NH \end{smallmatrix}$, is produced from alloxan and 1:2-diamidonaphthalene hydrochloride. It forms a yellow, microscopic powder, decomposes above 300° , does not dissolve in alkali carbonates, but is readily soluble in caustic alkalis; it is very sparingly soluble in water and only slightly more so in alcohol; the *barium salt* is a yellow precipitate, insoluble in water, and decomposes when dried in the desiccator.

When hot aqueous solutions of alloxantin and 3:4-diamidotoluene hydrochloride are mixed, tolualloxazine, identical with that described above, is formed.

Dimethyltolualloxazine, $C_8H_3Me \begin{smallmatrix} N:C \cdot NMe \cdot CO \\ | \\ N:C \cdot CO \cdot NMe \end{smallmatrix}$, is obtained when an excess of aqueous 3:4-diamidotoluene hydrochloride is added to a boiling aqueous solution of tetramethylalloxantin and the mixture boiled for a time. It does not show acidic properties; it crystallises from boiling water, in which it is sparingly soluble (0.5 gram requires for dissolution 2 litres of boiling water), in delicate, yellowish-white needles, but is best crystallised from boiling alcohol, which dissolves it more readily. It melts at $205-210^\circ$.

Dimethylalloxazine, $C_8H_4 \begin{smallmatrix} N:C \cdot NMe \cdot CO \\ | \\ N:C \cdot CO \cdot NMe \end{smallmatrix}$, is a yellowish-white, sandy, crystalline powder; it is very sparingly soluble in water, more readily in boiling alcohol, and melts at 236° .

Hydroxyquinoxalinecarboxylic acid, $C_8H_4 \begin{smallmatrix} N:C \cdot OH \\ | \\ N:C \cdot COOH \end{smallmatrix}$, is formed when aqueous solutions of 1:2-diamidobenzene and mesoxalic acid are heated; it separates from boiling water in delicate, yellow needles and decomposes at 200° ; the *barium salt* crystallises in needles.

Naphthazinehydroxycarboxylic acid, $C_{10}H_5 \begin{smallmatrix} N:C \cdot OH \\ | \\ N:C \cdot COOH \end{smallmatrix}$, is only sparingly soluble in boiling water; the *barium salt* is a yellowish, flocculent precipitate.

Toluquinoxalinecarboxylic acid, prepared from 3:4-diamidotoluene and mesoxalic acid, is identical with that described by Hinsberg (*loc. cit.*).

A. R. L.

Thiophen. By G. MINUNNI (*Gazzetta*, 21, 143-148).—When thiophen, prepared by Volhard and Erdmann's method, is heated with an equal weight of phenylhydrazine, evolution of hydrogen sulphide commences after a few minutes and continues for some hours, but on distilling the product nothing but unaltered thiophen and phenylhydrazine are obtained. Similar results are obtained on operating in a closed tube at 220° .

When the thiophen recovered from the above operations is heated at $200-210^\circ$ in a closed tube with litharge, no change is observed,

but when thiophen which has not been treated with phenylhydrazine is heated with litharge, lead sulphate is formed. From this it is evident that the evolution of hydrogen sulphide is due to the presence of some impurity in the thiophen.

If 1 part of phenylhydrazine be gradually dropped into 10 parts of the impure thiophen, a white, crystalline substance, soluble in excess of the base, is precipitated; this compound is not formed if thiophen which has been already heated with phenylhydrazine is employed. The crystalline compound thus formed is identical with the phenylhydrazine phenylthiocarbazine prepared by E. Fischer (*Annalen*, 190, 114) by the action of phenylhydrazine on carbon bisulphide. The impurity is therefore carbon bisulphide. Rectified thiophen contains an average of about 0.2 per cent. of this substance, and unrectified thiophen a much larger quantity.

The author records a very characteristic property of phenylhydrazine phenylthiocarbazine; on passing a current of dry oxygen through its solution in carbon bisulphide, hydrogen sulphide is evolved and diphenylthiocarbazine deposited as a white, crystalline powder.

E. v. Meyer (Abstr., 1886, 349) states that a mixture of phenylhydrazine and benzene deposits a crystalline compound containing sulphur and melting at 96° ; he considers its formation to be due to an impurity in the phenylhydrazine employed. This substance agrees in all its recorded properties with phenylhydrazine phenylthiocarbazine, and is most probably derived from carbon bisulphide in the benzene employed, as commercial benzene always contains this impurity.

W. J. P.

Note.—A short time before the publication of this paper, Liebermann and Seyewitz (this vol., p. 684) stated that the carbon bisulphide in commercial benzene could be estimated by means of its reaction with phenylhydrazine.

W. J. P.

Ring and Nucleus Structure of Aromatic Hydrocarbons.

By W. VAUBEL (*J. pr. Chem.* [2], 44, 137—149).—The author reviews the structural formulæ hitherto proposed for benzene, and regards Loschmidt's (*Monatsh.*, 11, 28; Abstr., 1890, 602) as the least objectionable of them. But even this does not express his ideas of the benzene molecule, for the summits of the tetrahedra are all in the same plane, a dissymmetry that is not warranted by the behaviour of benzene. None of the formulæ hitherto suggested complies with the fact that ortho- and para-derivatives are chiefly formed (1) when benzene and toluene are chlorinated and brominated; (2) when halogen substitution products of the methyl group in toluene are nitrated; (3) when chloro-, bromo-, and iodo-benzene are nitrated; (4) when acetanilide is nitrated, producing ortho- and para-nitraniline; (5) when phenol is nitrated, chlorinated, and sulphated; (6) when cinnamic and hydrocinnamic acids are nitrated. Nor does any of them comply with the facts that meta-derivatives are chiefly formed (1) when benzaldehyde, acetophenone, benzoic acid, and phenyl cyanide are nitrated; (2) when benzene is heated with fuming sulphuric acid at 200° , the metasulphonic acid at first formed being converted into the para-acid by longer heating.

The author's formula for benzene is a symmetrical arrangement of Loschmidt's formula, that is to say, instead of the summits of the six tetrahedra being all on the same side of the central plane, three of them are on each side. He explains away various difficulties by aid of this formula and develops it for naphthalene, in which case it complies with Bamberger's qualifications (*Annalen*, 257, 1; Abstr., 1890, 1299), and for anthracene. A. G. B.

Constitution of Cymene. By M. FILETI (*J. pr. Chem.* [2], 44, 150—152).—The author has repeated Widman's experiments (this vol., p. 986), and fully confirms his conclusion that cymene is an isopropyl derivative. A. G. B.

Metacyanobenzyl Chloride and Metacyanobenzaldehyde. By P. REINGLASS (*Ber.*, 24, 2416—2424).—Metacyanobenzyl chloride, $\text{CN}\cdot\text{C}_6\text{H}_4\cdot\text{CH}_2\text{Cl}$, is obtained by treating metacyanotoluene with chlorine at 150° until it has gained 30 per cent. in weight, spreading on a tile the reddish-yellow, crystalline cake which forms on cooling, and then dissolving it in a small quantity of boiling alcohol. It separates from alcohol in small, white plates or colourless prisms, and from boiling water in long, delicate needles, melts at 67° , boils at $258\text{--}260^\circ$ (760 mm.). It is also soluble in ether, chloroform, and benzene, and is slightly volatile with aqueous vapour. Its vapour has a strong action on the eyes and mucous membrane of the nose; whilst the substance itself produces an irritation on the skin, and a burning on the tongue.

Metacyanobenzal chloride, $\text{CN}\cdot\text{C}_6\text{H}_4\cdot\text{CHCl}_2$, is formed by treating metacyanotoluene with chlorine until it has gained 60 per cent. in weight; when the red product is distilled, it passes over with the evolution of hydrogen chloride between 272° and 275° (765 mm.) as a clear, yellow liquid.

Paracyanobenzal chloride, $\text{CN}\cdot\text{C}_6\text{H}_4\cdot\text{CHCl}_2$, is prepared by treating paracyanobenzyl chloride (Mellinghoff, Abstr., 1890, 239) with chlorine until it has gained 30 per cent. in weight; it is a colourless liquid boiling at $273\text{--}276^\circ$ (770 mm.).

Metacyanobenzyl cyanide, $\text{CN}\cdot\text{C}_6\text{H}_4\cdot\text{CH}_2\text{CN}$, is obtained by dissolving metacyanobenzyl chloride (6 grams) and potassium cyanide (3 grams) in water (25 c.c.) and alcohol (60 c.c.), heating the mixture on the water-bath for $\frac{3}{4}$ hour, distilling off two-thirds of the alcohol, and pouring the residue into water; the precipitated compound is crystallised from hot water; it forms delicate needles, melts at 84° , and is easily soluble in alcohol, ether, chloroform, and benzene.

m-Chlorometatoluamide, $\text{CONH}_2\cdot\text{C}_6\text{H}_3(\text{Cl})\cdot\text{CH}_2\text{Cl}$, is formed by dissolving metacyanobenzyl chloride in five times its weight of concentrated sulphuric acid and allowing it to remain for 15 hours (compare Gabriel, Abstr., 1887, 1038; Mellinghoff, *loc. cit.*), then pouring it into eight times its volume of water, neutralising with dilute ammonia, and crystallising the precipitated compound from a small quantity of hot alcohol. It melts at 124° , and is very readily soluble in alcohol, ether, and hot water. Its dust causes sneezing.

m-Chlorometatoluic acid, $\text{COOH}\cdot\text{C}_6\text{H}_3(\text{Cl})\cdot\text{CH}_2\text{Cl}$, is produced by heat-

ing metacyanobenzyl chloride with 20 times its weight of concentrated hydrochloric acid in a reflux apparatus, when the acid separates from the solution on cooling in small, delicate needles. To purify it, it is dissolved in dilute ammonia, filtered, and reprecipitated by the addition of hydrochloric acid. When recrystallised from hot water, it melts at 135° , and is readily soluble in alcohol and ether. The copper salt separates as a sparingly soluble, bright blue precipitate on adding copper sulphate to an aqueous solution of the ammonium salt.

Metacyanobenzylphthalimide, $\text{CN}\cdot\text{C}_6\text{H}_4\cdot\text{CH}_2\cdot\text{N}\cdot\text{C}_6\text{H}_4\text{O}_2$, is prepared by heating an intimate mixture of dry metacyanobenzyl chloride (7 grams) and potassium phthalimide (9 grams) in a globular flask at $125\text{--}130^{\circ}$ for 3—4 hours; when cold, the product is boiled with water and the solution filtered while hot; the granular powder which separates from the filtrate is purified by crystallising it from glacial acetic acid; it melts at 147° .

o-Amidometatoluic acid, $\text{COOH}\cdot\text{C}_6\text{H}_4\cdot\text{CH}_2\cdot\text{NH}_2$, is obtained by heating the last-described imide (2 grams) with concentrated hydrochloric acid (10 c.c.) at 200° for 3 hours in a sealed tube, diluting the product with a little water, filtering off the phthalic acid, and isolating the new acid from the filtrate by means of its mercuric salt, which is sparingly soluble in water; this is decomposed by a current of hydrogen sulphide, sodium acetate added to the filtrate, and the liquid slowly evaporated, when the acid separates in small, white scales which melt at $215\text{--}218^{\circ}$. An intermediate compound, *metacarboxybenzylphthalamic acid*, $\text{COOH}\cdot\text{C}_6\text{H}_4\cdot\text{CH}_2\cdot\text{NH}\cdot\text{CO}\cdot\text{C}_6\text{H}_4\cdot\text{COOH}$, is formed by heating the phthalimide (5 grams) with 30 per cent. sodium hydroxide (40 c.c.) for 20—25 minutes, shaking frequently, and then adding water and an excess of hydrochloric acid, when it is precipitated; when recrystallised from hot alcohol, it melts at $228\text{--}230^{\circ}$ (compare Günther, Abstr., 1890, 977). If this compound is heated with concentrated hydrochloric acid at 200° in a sealed tube for 3 hours, *o*-amidometatoluic acid is formed. The *platinochloride*, $(\text{C}_6\text{H}_4\text{NO}_2)_2\cdot\text{H}_2\text{PtCl}_6$, is a yellow ochreous precipitate, and the *aurochloride* forms yellow prisms and melts at $175\text{--}177^{\circ}$ with decomposition.

Dimetacarboxybenzyl ether, $\text{O}(\text{CH}_2\cdot\text{C}_6\text{H}_4\cdot\text{COOH})_2$, is obtained by heating metacyanobenzyl chloride (5 grams) with 33 per cent. potassium hydroxide in a reflux apparatus for 3 hours, diluting with water, and, after precipitating the filtrate with an excess of hydrochloric acid, crystallising from hot water; it melts at 180° , and is sparingly soluble in ether, chloroform, and benzene.

Metacyanobenzaldehyde, $\text{CN}\cdot\text{C}_6\text{H}_4\cdot\text{COH}$, is produced by adding metacyanobenzyl chloride (8 grams) to a hot solution of copper nitrate (16 grams) in water (160 c.c.) and boiling for 16—17 hours, when an intensely green solution is obtained; on cooling, this deposits white needles, which are dissolved in ether, and the ethereal solution mixed with an aqueous solution of sodium hydrogen sulphite; the additive compound is collected, washed with ether and alcohol, and steam distilled in the presence of an alkali; the distillate is extracted with ether, which leaves long needles on evaporation. It melts at $79\text{--}81^{\circ}$, yields a metallic mirror with ammoniacal silver nitrate, and gives all the reactions of an aldehyde. The *hydrazone*, $\text{CN}\cdot\text{C}_6\text{H}_4\cdot\text{CH}\cdot\text{N}\cdot\text{NHPh}$,

crystallises from alcohol in small, yellow needles, and melts at 120° ; the *oxime*, $\text{CN}\cdot\text{C}_6\text{H}_4\cdot\text{CH}\cdot\text{NOH}$, melts at $99\text{--}101^{\circ}$, and yields metacyanobenzene (m. p. 157°) on treatment with acetic anhydride.

Paracyanobenzaldehyde, $\text{CN}\cdot\text{C}_6\text{H}_4\cdot\text{COH}$, is obtained from paracyanobenzyl chloride; it crystallises from hot water in long, white needles, melts at $96\text{--}98^{\circ}$, is volatile with steam, and is readily soluble in alcohol, ether, and chloroform. The *hydrazone* melts at $135\text{--}137^{\circ}$, and the *oxime* at 145° .

Both the last-described aldehydes may be prepared more quickly and a better yield obtained by boiling the corresponding benzal chlorides with silver nitrate.

Paralehydrobenzoic acid, $\text{COOH}\cdot\text{C}_6\text{H}_4\cdot\text{COH}$, is formed on heating paracyanobenzaldehyde with 25 times its weight of concentrated hydrochloric acid in a reflux apparatus; it crystallises in microscopic needles, commences to melt at 285° , and is soluble in water, but more so in alcohol and ether. The *copper salt* is a bright blue precipitate; the *oxime* melts at $208\text{--}210^{\circ}$, whilst the *hydrazone* melts at $212\text{--}214^{\circ}$.

Metaldehydobenzoic acid is obtained from metacyanobenzaldehyde in a similar manner to its isomeride; it melts at $164\text{--}166^{\circ}$; the *copper salt* is a greenish-blue precipitate; the *oxime* melts at 165° with decomposition, whilst the *hydrazone* melts at $112\text{--}115^{\circ}$. Orthaldehydobenzoic acid (phthalaldehydic acid) has been described by Racine (Abstr., 1886, 549).

A. R. L.

Products of Condensation of Metanitrobenzaldehyde with Phenol and Resorcinol. By G. DE VARDA and M. ZENONI (*Gazzetta*, 21, 174—183; compare this vol., p. 1378).—*Metanitrodioxytriphenylmethane*, $\text{CH}(\text{C}_6\text{H}_4\cdot\text{OH})_2\cdot\text{C}_6\text{H}_4\cdot\text{NO}_2$, is obtained by melting together a mixture of phenol and metanitrobenzaldehyde in theoretical proportion, slowly adding sulphuric acid ($\text{H}_2\text{SO}_4 + 2\text{H}_2\text{O}$), 1 mol., then gradually heating and keeping the mixture at 130° , until no further action is observed. The product is freed from unaltered phenol and metanitrobenzaldehyde by steam distillation, boiled with a large quantity of water, and the solution filtered and allowed to remain; on cooling, the condensation product is deposited. It is an amorphous, dark-yellow powder, melting at $59\text{--}60^{\circ}$, very little soluble in ether, chloroform, benzene, or light petroleum, and almost insoluble in carbon bisulphide, soluble in about 10,000 parts of boiling water. It is not volatile with steam, and is for the most part decomposed on distillation under diminished pressure.

Metanitrophenyldiresorcinolmethane, $\text{CH}[\text{C}_6\text{H}_3(\text{OH})_2]_2\cdot\text{C}_6\text{H}_4\cdot\text{NO}_2$, is readily obtained without the aid of a condensing agent by heating the equivalent proportions of resorcinol and metanitrobenzaldehyde at 150° , and purifying the product by washing it with water and precipitation from its alcoholic and ethereal solutions. It is a yellowish, amorphous powder, slowly darkened by the action of air and light, and melts at $97\text{--}100^{\circ}$; it is soluble in ether, alcohol, and acetic acid, almost insoluble in light petroleum, benzene, chloroform, and carbon bisulphide; it is precipitated unaltered from its alkaline solution by acids. The substance cannot be distilled with steam, or under diminished pressure.

The precise constitutions of the above two compounds are unknown.
W. J. P.

Methylation of Symmetrical Orcinol. By A. KRAUS (*Monatsh.*, 12, 191—204; compare Herzig and Zeisel, *Abstr.*, 1890, 1405).—Anhydrous orcinol melts at 106·5—111° or on remelting after solidification at 108—111°; on warming with methyl iodide and potash in methyl alcoholic solution, and treatment of the product with potash, a dimethylorcinol is obtained on acidifying and extracting with ether; it has the formula $C_6HMe_2(OH)_2$ [$OH = 2 : 3$; $Me_2 = 2 : 4 : 5$] or $OH \cdot C \begin{smallmatrix} \text{CH} \cdot CMe \\ \text{CMe}_2 \cdot CO \end{smallmatrix} CH$, crystallises from methyl alcohol, and melts at 204°. The *acetyl*, *benzoyl*, and *bromo*-derivatives are viscid liquids.

The portion of the original methylation product which is insoluble in potash, on distillation under reduced pressure, yields *dimethylorcinol dimethyl ether*, $C_6HMe_2(OMe)_2$; this crystallises from glacial acetic acid, and melts at 93—94°. The fraction boiling at 135—138° under a pressure of 18—22 mm. was treated with hydriodic acid, and the product formed, when purified, melted at 156°. This is a *dimethylorcinol* isomeric with the one above described, as it contains two hydroxyl groups. Since it is prepared from the dimethyl ether, it probably has the first of the two formulæ given above, whilst the compound melting at 204° is probably represented by the second. J. B. T.

Action of Light on Anethoil. By G. DE VARDA (*Gazzetta*, 21, 183—188).—Crystalline anethoil, when exposed to sunlight, soon liquefies, and, on submitting it to distillation, a fraction boiling between 251° and 296° is obtained. This solidifies on cooling, and, when purified by repeated crystallisation from strong alcohol, is found to be a new polymeride of anethoil, which the author terms *photoanethoil*. The residue left in the retort, when crystallised from alcohol, yields the same substance.

Photoanethoil forms minute, white, nacreous, tabular crystals, melts at 207°, and has neither taste nor odour. It is insoluble in water, sparingly soluble in ether, alcohol, light petroleum, chloroform, and boiling acetic acid, sublimes in microscopic plates, and does not volatilise with aqueous vapour. Its solution in chloroform has no rotatory action on polarised light. Anethoil yields about 0·5 per cent. of photoanethoil by the above treatment.

Metanitrophenyldianethoilmethane, $NO_2 \cdot C_6H_4 \cdot CH[C_6H_3(C_2H_5) \cdot OMe]_2$, is obtained when the theoretical proportions of anethoil and meta-nitrobenzaldehyde are fused together with sulphuric acid ($H_2SO_4 + H_2O$) at 150°. The crude product is boiled out with water and treated with superheated steam; the residue is then extracted with ether, and the solution filtered and poured into alcohol; the precipitate thus formed is collected, again dissolved in ether, and reprecipitated by the addition of light petroleum. The pure substance is a yellow, amorphous powder without odour or taste, melts at 165—170°, is insoluble in alkalis and sulphuric acid, almost insoluble in alcohol, fairly soluble in chloroform, ether, carbon bisulphide, and acetic acid. It does not sublime on heating, and cannot be distilled in a current of steam.

When photoanethoil is heated with metanitrobenzaldehyde and acid, the same condensation product is produced, showing that photoanethoil is a true polymeride of anethoil. W. J. P.

Constitution of Quinone. By J. U. NEF (*Amer. Chem. J.*, 13, 422—428; compare Abstr., 1890, 1270).—In his previous paper (Abstr., 1890, 1270), the author pointed out that Fittig's formula must represent the constitution of quinone. It has been asserted, however, that the proof that quinone dibromide has its bromine atoms in the ortho-position is not absolute (compare Claus, this vol., p. 44; Nietzki, *ibid.*, 189; Kehrmann, *ibid.*, 432).

The analogy between the behaviour of quinone dibromide and tetrabromide towards zinc-dust and acetic acid (Abstr., 1890, 1272) and the behaviour of v. Baeyer's additive products of hydrogenated terephthalic acids (Abstr., 1888, 1069; 1889, 1176; *Annalen*, 258, 11) is such that there can be little doubt that these compounds are of similar constitution.

Since no orthodibromoquinone is formed when hydrogen bromide is removed from quinone tetrabromide by boiling it with aqueous alcohol (Abstr., 1890, 1272), the hydrogen bromide must be split off from the ortho-position, and it is rendered highly probable that the addition of bromine takes place in ortho-positions; the existence of the following compounds furnishes absolutely conclusive proof that this is the case:—

Quinone dichloride [$O_2 : Cl_2 = 1 : 4 : 2 : 3$] is pale yellow, melts at 143° , and distils unchanged.

Quinone tetrachloride [$O_2 : Cl_4 = 1 : 4 : 2 : 3 : 5 : 6$] is colourless, sublimes without melting, and undecomposed.

Quinone dichloride dibromide [$O_2 : Cl_2 : Br_2 = 1 : 4 : 2 : 3 : 5 : 6$] is colourless, and melts at 195° .

The properties of these substances are similar to those of the two bromine additive products (Abstr., 1890, 1272), except that they are more stable. That the constitution of the dichloride dibromide is as given above, and not $O_2 : Cl_2 : Br_2 = 1 : 4 : 3 : 6 : 2 : 5$, is proved by the fact that, when boiled with alcohol and water, it yields about equal parts of *meta*- and *para*-chlorobromoquinone of the constitution $O_2 : Cl : Br = 1 : 4 : 6 : 2$ and $1 : 4 : 3 : 6$ respectively. The latter crystallises in plates which melt at 172° , the former in needles melting at 113° ; they were easily separated by fractional crystallisation from ether, in which the *para*-compound is less soluble. The direct synthesis of these two substances in the following ways proves that their constitution is correctly given above.

(a.) Parachlorobromonitrobenzene [$NO_2 : Cl : Br = 1 : 2 : 5$] was reduced by zinc-dust and acetic acid to chlorobromaniline (m. p. 43°), which, on boiling with manganese dioxide and sulphuric acid, gave parachlorobromoquinone, identical with the above product and with Levy and Schultz's chlorobromoquinone (Abstr., 1882, 509).

(b.) Chloroparanitrophenol [$OH : Cl : NO_2 = 1 : 2 : 4$] was converted into bromochloroparanitrophenol [$OH : Cl : NO_2 : Br = 1 : 2 : 4 : 6$] (m. p. 138°) and then reduced with tin and hydrochloric acid. The chlorobromamidophenol thus produced was boiled with

manganese dioxide and sulphuric acid, when metachlorobromoquinone, identical with the above, was obtained.

If quinone dichloride dibromide has its chlorine atoms in the para-position [2:5] and it be decomposed by aqueous alcohol, assuming the splitting off of halogen hydride to take place in great part from ortho-positions, the compound produced would be paradichloroquinone (m. p. 164°) since the chlorine atoms are more firmly bound than the bromine atoms. Paradibromoquinone (m. p. 188°) and metachlorobromoquinone are the other possible products. As a fact, however, neither paradichloro- nor paradibromo-quinone was formed.

If, however, the quinone dichloride dibromide have the constitution assigned to it above, and halogen hydride be split off from para-positions, only orthochlorobromoquinone and metachlorobromoquinone could be formed.

The addition of halogens to quinone is thus proved to take place in ortho-positions, and the splitting off of halogen hydride also to take place from ortho-positions—facts which are explicable by Fittig's formula for quinone, but will not uphold Claus' diagonal ketone formula.

The publication of experimental details is promised, and the author concludes with the observation that it seems probable to him that the conversion of quinol into quinone is accompanied by a rearrangement of the valencies of the carbon atoms forming the closed chain (Nietzki, *loc. cit.*), on the ground that neither quinolcarboxylic acid, tolylquinolcarboxylic acid, paradihydroxyterephthalic acid, nor the ethyl salts of these acids, can be oxidised to the corresponding quinones.

A. G. B.

Euxanthone. By J. HERZIG (*Monatsh.*, 12, 161—171).—The author has studied various derivatives of euxanthone with the object of showing its relationship to quercetin. Both these substances are yellow, but yield colourless acetyl derivatives which are readily hydrolysed by treatment with sulphuric acid.

Euxanthone ethyl ether, $C_{13}H_7O_2 \cdot OEt$, crystallises from alcohol in long, yellow needles, and melts at 144—145°. It does not dissolve in potash, but yields an unstable, insoluble salt by the action of alcoholic potash; the latter resembles the corresponding quercetin derivative, and readily undergoes dissociation in presence of water. *Acetyl euxanthone ethyl ether*, $C_{13}H_5AcO_2 \cdot OEt$, crystallises from alcohol in long, colourless, lustrous needles, and melts at 180—182°. The compound readily yields a euxanthone diethyl ether, $C_{13}H_7O_2(OEt)_2$, on treatment with potash and ethyl iodide. Euxanthone ethyl ether is formed from the diethyl derivative when the latter is heated with alcoholic potash in a sealed tube for four hours at 130—150°. An isomeric *monethyl ether* is obtained by treating the diethyl derivative with 20 parts of concentrated sulphuric acid for three hours at 100°; it crystallises from alcohol in colourless needles, melts at 223—225°, and is readily soluble in dilute potash. The constitution of this compound is being further investigated. The existence of two mon-ethyl ethers makes it appear possible that euxanthone may exist in

two forms, represented by the formulæ $O < \begin{smallmatrix} C(OH) \cdot C_6H_3 \cdot OH \\ C_6H_3 - O \end{smallmatrix}$ and $CO < \begin{smallmatrix} C_6H_3(OH) \\ C_6H_3(OH) \end{smallmatrix} > O$, or it may be that the hydroxyl groups occupy different relative positions in the molecule. That there is considerable difference between euxanthone and quercetin is proved by the fact that, whilst the latter is readily decomposed by alkalis, euxanthone is unacted on when heated with potash at 150° in a sealed tube.

J. B. T.

Synthesis of Aromatic Mercaptans. By G. LUSTIG (*Gazzetta*, 21, 213—216).—Lenckart (Abstr., 1890, 603) has shown that thiophenols may be prepared by the action of potassium ethyl xanthate on diazo-compounds. The author finds it more convenient to employ the red salt, $OH \cdot OS \cdot SK$, obtained by the action of carbon bisulphide on caustic potash in place of potassium ethyl xanthate.

The red salt obtained by digesting 14 grams of solid potassium hydrate with excess of carbon bisulphide, is dissolved in 100 c.c. of water, heated at $70-75^\circ$, and a solution of diazobenzene chloride, prepared from 20 grams of aniline, slowly run into it; a yellow substance is thus formed which decomposes into an oil with evolution of nitrogen. The oil is soluble in acetic acid, alcohol, light petroleum, and ether, but insoluble in potash and dilute acids; no analysis could be made, as the oil could not be purified. On steam distillation, it yields thiophenol and diphenyl bisulphide. When boiled with either aqueous or alcoholic potash and treated with acid, the oil yields 65—75 per cent. of thiophenol.

When paramonacetylphenylenediamine is diazotised, and treated with the red salt in the manner just described, a solid product, melting at $115-120^\circ$, is formed corresponding with the oil obtained from diazobenzene chloride. This, on hydrolysis with 1 mol. of alcoholic potash, yields paradithioacetylphenylamine, and with 2 mols. paradithiophenylamine, compounds which were recognised by the reactions given by Lenckart.

W. J. P.

Nomenclature of Compounds containing Two Atoms of Nitrogen Linked together. By T. CURTIUS (*J. pr. Chem.* [2], 44, 96—101).—The necessity for a systematic nomenclature for hydrazine derivatives and for fatty diazo-compounds has been evident for some time past, and, with the object of avoiding further confusion, the author proposes to adopt the following means of distinguishing compounds which contain two nitrogen atoms, either singly or doubly linked. The nomenclature is not applicable to the numerous derivatives of hydrazine which contain several carbon atoms united with the two nitrogen atoms in the form of a "ring." (1.) For the radicle $\cdot N \cdot N \cdot$ the term *azi-* is proposed; this being written *-azine* at the end of a word. (2.) For the radicle $\cdot N \cdot N \cdot$ the name *azo-* is retained, but is written *-azone* at the end of a word. (3.) The partial or complete saturation of these radicles by hydrogen is indicated by the prefix *hydr-*, the terms becoming *hydrazo-* or *hydrazone-*, or, at the ends of words, *-hydrazine* or *-hydrazone*, as the case may be. All known

azo-, diazo-, and hydrazine-derivatives can readily be distinguished as derivatives either of the as yet unknown hydrazone or diimide, $\text{NH}\cdot\text{NH}$, or of hydrazine, $\text{NH}_2\cdot\text{NH}_2$, and numerous applications of the proposed nomenclature are given in the paper.

The substitution of the azi- and azo-radicles for hydrogen in methane and ammonia would lead to the formation of four 3-membered rings, one of which only has hitherto been isolated, although derivatives of all four have been prepared. These rings are distinguished thus :—

As an instance of the application of the proposed nomenclature, the change of name from ethyl diazoacetate to ethyl azomethylene-carboxylate may be quoted.

W. P. W.

Action of Benzylamine on Glycol Chlorhydrin. By G. GOLDSCHMIEDT and R. JAHODA (*Monatsh.*, 12, 81—85).—When molecular proportions of benzylamine and glycol chlorhydrin are heated together at 100° in a reflux apparatus, a vigorous action takes place, and the contents of the flask become dark-red. On cooling, the product solidifies to a yellow, waxy mass, which contains benzylamine hydrochloride and hydroxyethylbenzylamine. On heating the latter with hydrochloric acid at 170° for five hours, it is converted into chloroethylbenzylamine hydrochloride, $\text{CH}_2\text{Ph}\cdot\text{NH}\cdot\text{CH}_2\cdot\text{CH}_2\text{Cl}$, which crystallises in white needles, melts at 192° , and is readily soluble in water, alcohol, and chloroform.

When the yellow, waxy mass is heated in open flasks or closed tubes with sulphuric acid, or with zinc chloride, benzylamine and benzylmorpholine, $\text{CH}_2\text{Ph}\cdot\text{N} < \begin{array}{c} \text{CH}_2\cdot\text{CH}_2 \\ \text{CH}_2\cdot\text{CH}_2 \end{array} > \text{O}$, are produced. The latter crystallises in slender needles, and has an odour resembling that of ammonia; it forms a *hydrochloride*, $\text{C}_{11}\text{H}_{15}\text{NO}\cdot\text{HCl}$, which dissolves readily in water and in alcohol, and melts at about 200° ; also a *platinochloride*, $(\text{C}_{11}\text{H}_{15}\text{NO})_2\cdot\text{H}\cdot\text{PtCl}_6$, which is only sparingly soluble in water, crystallises in reddish-yellow needles, and decomposes at 192° .

The condensation occurring in the preparation of benzylmorpholine takes place between two hydroxyl groups with elimination of the elements of water, and not between chlorine and hydroxyl, as in the syntheses of morpholine derivatives effected by Knorr (*Abstr.*, 1889, 1218).

G. T. M.

Commercial Pseudocumidine. By H. KRÖMER (*Ber.*, 24, 2407—2415).—The author's experiments were made with two different specimens of commercial pseudocumidine. The first, melting at 63° , yielded durylonitrile when treated by Sandmeyer's method; whilst the second, melting at a higher temperature, on similar treatment, gave an oil having a strong, phenolic odour, from which durylonitrile and mesitylrol, melting at 68 — 69° , were obtained.

Cumobenzylamine, $C_6H_5Me_3CH_2NH_2$, is formed exclusively on reducing the nitrile from the pseudocumidine melting at 63° by Ladenberg's method with sodium and absolute alcohol. When the reduction is complete, water is added, the solution acidified with hydrochloric acid, the alcohol distilled off, and, after adding an excess of potash, the base is driven over in a current of steam. It crystallises from alcohol in groups of long, friable needles, melts at 64.5° , and is sparingly soluble in hot water, more readily in alcohol and chloroform. The *hydrochloride*, $C_{10}H_{15}N.HCl$, forms short, thick prisms and needles, melts at $240-242^\circ$ with decomposition, and is fairly soluble in cold water; the *sulphate* forms colourless plates, melts at 238° , and is sparingly soluble in water; the *platinochloride*, $(C_{10}H_{15}N)_2H_2PtCl_6$, is a reddish-yellow, crystalline powder decomposing at $208-209^\circ$; the *mercuriochloride*, $C_{10}H_{15}N.HHgCl_2$, crystallises in needles, melts at $141-142^\circ$, and is sparingly soluble in cold water, readily in hot; the *picrate*, $C_{10}H_{15}N.C_6H_3(NO_2)_3.OH$, separates from hot water in long, yellow needles; the *bismuthiodide*, $C_{10}H_{15}N.HBiI_4$, is a microcrystalline powder, readily soluble in cold alcohol; whilst the *aurochloride* decomposes on boiling with water.

Cumobenzyl alcohol, $C_6H_5Me_3CH_2OH$, is obtained when a concentrated solution of cumobenzylamine hydrochloride is treated with a slight excess of the theoretical quantity of sodium nitrite in the cold, the solution being finally heated for a short time on the water-bath. The aqueous liquid, on the surface of which a dark-coloured oil floats, is extracted with ether when cold, and the oily residue obtained on distilling the ethereal solution is dissolved in hot alcohol, and repeatedly recrystallised, when the compound is obtained in pale-yellow needles. It melts at 168° , and is almost insoluble in water, more easily in alcohol and ether.

Hemimellitbenzylamine, $C_6H_5Me_3CH_2NH_2$, was obtained as chief product from the pseudocumidine of higher melting point, and is isolated in the same manner as cumobenzylamine (see above), but, as it is more soluble in water, the distillate obtained on driving the base over with steam must be extracted with ether. The ethereal solution is distilled, and the crude base converted into the hydrochloride, from which the pure base is obtained on decomposition with potash and crystallisation from hot water. It forms small plates having a silvery lustre, but these change to an amorphous powder when kept in the desiccator, and it then melts at 123° . The *hydrochloride* forms delicate needles, melts at 270° , and is sparingly soluble in cold water and in alcohol; the *platinochloride* separates from hot dilute hydrochloric acid in rhombic dodecahedra and melts at $219-220^\circ$; the *aurochloride*, $C_{10}H_{15}N.HAuCl_4$, crystallises from boiling water containing hydrochloric acid in garnet-red prisms, and melts at $162-165^\circ$ with decomposition; the *mercuriochloride* forms a felt-like mass of needles, and melts at $240-241^\circ$; whilst the *picrate* separates from alcohol in long, yellow needles, and melts at 239.5° with partial decomposition. Potassium bismuth iodide, potassium cadmium iodide, and iodine dissolved in potassium iodide solution yield sparingly soluble derivatives.

Hemimellitbenzyl alcohol, $C_6H_5Me_3CH_2OH$, is prepared from the

last-described amido-compound by a process similar to that used for cumobenzyl alcohol (see above); it crystallises from dilute alcohol in long needles, melts at 78° , and is sparingly soluble in water, readily in alcohol and ether.

Hemimellibenzaldehyde, $C_8H_7Me_3COH$, is obtained when the alcohol is suspended in dilute sulphuric acid, and a dilute solution of the calculated quantity of potassium dichromate dropped in. After remaining at the ordinary temperature for several hours, it is steam distilled, and the solid distillate crystallised from dilute alcohol; it forms needles, melts at 52° , and exhibits all the reactions of an aldehyde.

The nitrile obtained from the pseudocumidine of higher melting point, on hydrolysis with alcoholic potash, gave durylic acid melting at $149-150^{\circ}$ and α -isodurylic acid melting at 203° ; these were separated by fractional crystallisation of their potassium salts.

The author has prepared pseudocumidine melting at 63° by treating the commercial substance with nitric acid, as directed by Hofmann, but this yielded (by Sandmeyer's method) mesitylol and a cyanide, from which the two last-mentioned acids were obtained. This can only be explained, if Hofmann's method is trustworthy, by assuming a migration of the methyl groups, but, if otherwise, the commercial base would appear to be a mixture of pseudocumidine and mesidine; hemimellidine must also be considered as a constituent, and, indeed, the latter must have been present in considerable quantity in the above-mentioned commercial base melting at the higher temperature.

A. R. L.

Action of Ammonia on Ortho-xylene Bromide. By M. SCHOLTZ (*Ber.*, 24, 2402-2407).—*Di-xyleneammonium bromide*,

$C_6H_4\left<\begin{smallmatrix} CH_2 \\ CH_2 \end{smallmatrix}\right>NBr\left<\begin{smallmatrix} CH_2 \\ CH_2 \end{smallmatrix}\right>C_6H_4$, is obtained when ortho-xylene bromide (3 grams) is heated at 120° with 10 times its weight of concentrated ammonia; it forms large, prismatic crystals, is not decomposed when boiled with potassium hydroxide solution, but when shaken with an excess of silver oxide and the filtrate evaporated, deliquescent crystals of the *hydroxide*, $N(C_6H_5)_2OH$, remain. This has all the properties of an ammonium hydroxide, its solutions having a strongly alkaline reaction, absorbing carbonic anhydride, and liberating ammonia from ammonium chloride on boiling; it furnishes the first example of an ammonium base with two bivalent alcohol radicles. The *aurochloride*, $C_{18}H_{16}N_2AuCl_4$, forms delicate needles, melts at 197° , and is very sparingly soluble; the *platinochloride*, $(C_{16}H_{14}N)_2PtCl_6$, melts at 249° , and is almost insoluble in boiling water; whilst the *mercuriochloride* has the composition

The *iodide*, $N(C_6H_5)_2I$, separates when the hydroxide is neutralised with hydriodic acid; it crystallises in long needles, and is much less soluble than the bromide. The *periodide*, $N(C_6H_5)_2I_3$, separates as a brown precipitate when solution of iodine in hydriodic acid is added to an aqueous solution of the iodide; this crystallises from alcohol in violet needles having a metallic lustre; whilst the *perbromide* forms small, golden-yellow plates, and is very unstable.

Ortho-xylene bromide reacts with ammonia, even at 100°; when, however, the temperature is raised above 120°, an oily product yielding a crystalline base on purification is obtained. The latter is advantageously prepared by heating di-xylene ammonium bromide for eight hours in a sealed tube at 170°. It is a secondary base of the composition C_8H_7N , crystallises from alcohol in long needles, melts at 79—80°, and distils without decomposition between 130° and 135° under a pressure of 12 mm. It forms two *hydrochlorides*, $(C_8H_7N)_2 \cdot HCl$ and $C_8H_7N \cdot HCl$, which are obtained when the base is suspended in water and hydrogen chloride passed through the mixture until the base just dissolves; the *picrate*, $C_8H_7N \cdot C_6H_3N_3O_7$, crystallises in yellow needles; a *hydrobromide*, $(C_8H_7N)_2 \cdot HBr$, was also obtained. An *ammonium iodide*, $C_8H_7NMe_2I$, is formed when the base is treated with methyl iodide. The fact that the base forms two series of salts indicates that its molecular formula is twice that above given, and this was confirmed by a determination of the molecular weight by Raoult's method, employing phenol as solvent. It appears, therefore, to have the constitution $C_6H_4 < \begin{smallmatrix} CH_2 \cdot NH \cdot CH_2 \\ CH_2 \cdot NH \cdot CH_2 \end{smallmatrix} > C_6H_4$.

When either meta- or para-xylene bromide are heated with ammonia at 100°, a yellow, amorphous, non-nitrogenous substance, containing bromine, is formed; this is insoluble in every solvent which was tried; even when it is purified by washing with acids and alcohol, it did not yield concordant results on analysis. A. R. L.

Ladenburg's Method for Distinguishing Orthodiamines. By G. MAZZARA and A. LEONARDI (*Gazzetta*, 21, 256).—In the communication an abstract of which appears on p. 1364, it was shown that on heating diamidothymol hydrochloride with benzaldehyde, hydrogen chloride is evolved below 100°, the ortho-position of its hydroxyl relatively to an amido-group allowing it to behave like an orthodiamido-compound, giving rise to a benzenyl derivative. Diamidocarvacrol hydrochloride [Me : OH : $NH_2 \cdot HCl$: Pr : $NH_2 \cdot HCl$ = 1 : 2 : 3 : 4 : 5] and orthamidophenol hydrochloride also evolve hydrogen chloride on heating at 100° with benzaldehyde, probably owing to the formation of the corresponding benzenyl derivatives. Ladenburg's criterion for orthodiamines (*Abstr.*, 1878, 571), which depends on the evolution of hydrogen chloride on heating with benzaldehyde at 100°, is, therefore, not characteristic of those compounds, and is satisfied by orthamidophenols, and by those diamidophenols which have the hydroxyl groups in the ortho-position with respect to an amido-group.

S. B. A. A.

Constitution of Isomeric Oximes. By G. MINUNNI (*Gazzetta*, 21, 113—136).—The author criticises adversely the current theories of the isomerism of oximes, and considers that the isomerism may be satisfactorily explained without the assumption of space formulæ; he regards the conversion of one oxime into its isomeride as due to the formation and subsequent decomposition of an intermediate additive product with the agent producing intramolecular change. Thus the conversion of α - into β -benzaldoxime may be represented as follows:—

The existence of α -, β -, and γ -benzildioximes is explained in a similar manner.

The absence of isomerides among the fatty oximes is attributed to the unfavourable distribution of the atomic bonds among the carbon atoms contiguous to the oximido-group.

W. J. P.

Note.—A reply to this paper has been published by Hantzsch (this vol., p. 823), and Cramer has obtained isomeric oximidodisuccinic acids (this vol., p. 824).

W. J. P.

Action of Hydrazine Hydrate on Ketones and Ortho-diketones. By T. CURTIUS and K. THUN (*J. pr. Chem.* [2], 44, 161—186).—When hydrazine hydrate (1 mol.) is added to a ketone (2 mols.), derivatives of azimethylene, $\text{CH}_2 \cdot \text{N} \cdot \text{N} \cdot \text{CH}_2$, ketazines, are obtained; these compounds are more stable on heating, or when heated with reducing agents, than the aldazines (Abstr., 1889, 393), but less so with dilute acids; they are not decomposed by hot alkalis, do not reduce Fehling's solution, and only act on ammoniacal silver solution on protracted boiling (see below).

Bidimethylazimethylene, $\text{CMe}_2 \cdot \text{N} \cdot \text{N} \cdot \text{CMe}_2$, is obtained by gradually adding hydrazine hydrate (10 grams) to cooled acetone (22 grams). The product is dried over potash and fractionated, when nearly the whole passes over at 131° , the yield being 16.5 grams. It is a transparent, highly refractive liquid of a penetrating odour, and has a sp. gr. of 0.8365 at 21.5° ; it is miscible in all proportions with water, alcohol, and ether; mineral acids and also picric acid decompose it in the cold into hydrazine and acetone.

Bimethylethylazimethylene, $\text{CMeEt} \cdot \text{N} \cdot \text{N} \cdot \text{CMeEt}$, is formed on adding hydrazine hydrate (10 grams) to methyl ethyl ketone (27 grams); heat is developed, causing the mixture to boil; it is purified as in the case of the dimethyl derivative. It boils at 167 — 172° (at 75° under a pressure of 12 mm.), and closely resembles the dimethyl derivative, but has a less intense odour, and is more sparingly soluble in water; its sp. gr. is 0.8335 at 24° .

Bimethylpropylazimethylene, $\text{CMePr} \cdot \text{N} \cdot \text{N} \cdot \text{CMePr}$, is prepared from methyl propyl ketone. It boils at 195 — 200° (at 95° under a pressure of 12 mm.), is sparingly soluble in water, and has an odour recalling that of peppermint; its sp. gr. is 0.8335 at 24° .

Bimethylhexylazimethylene, $\text{C}_6\text{H}_{13} \cdot \text{CMe} \cdot \text{N} \cdot \text{N} \cdot \text{CMe} \cdot \text{C}_6\text{H}_{13}$, prepared from methyl hexyl ketone, is a pale-yellow oil of a basic odour; its sp. gr. is 0.8300 at 24° , and it boils at 286 — 290° (at 150° under a pressure of 12 mm.).

Bidiethylazimethylene, $\text{CEt}_2 \cdot \text{N} \cdot \text{N} \cdot \text{CEt}_2$, from diethyl ketone, boils at 190 — 195° (at 92° under a pressure of 12 mm.). Its odour resembles that of the dimethyl derivative, and its sp. gr. is 0.836 at 24° .

Bimethylphenylazimethylene, $\text{CMePh} \cdot \text{N} \cdot \text{N} \cdot \text{CMePh}$, formed when hydrazine hydrate is heated with acetophenone in a sealed tube at

100° for 12 hours. The solid product when crystallised from alcohol yields anisotropic prisms. It melts at 121°, boils above 360° without decomposition, and is easily soluble in hot alcohol, sparingly in cold, and insoluble in water.

Curtius has already suggested (Abstr., 1889, 1157) that the compounds obtained from benzile and hydrazine hydrate probably contain the group $\text{NH}\cdot\text{NH}$, and the present experiments support this. The authors have now submitted these compounds to a closer examination, and regard them as derivatives of hydrazimethylene; they have also studied similar derivatives of other orthodiketones (compare also this vol., p. 1350).

Dimethylbihydrazimethylene, $\text{N}_2\text{H}_2\cdot\text{CMe}\cdot\text{CMe}\cdot\text{N}_2\text{H}_2$, is produced by gradually adding hydrazine hydrate (2.5 grams) to diacetyl (2 grams) with cooling. When half the hydrate has been added, the melt solidifies, probably owing to the formation of the monhydrazide-derivative, so that it is necessary to heat the mixture whilst the rest of the hydrazine is being added. The solid product crystallises from alcohol in colourless, lustrous prisms, melts at 158°, and is very easily soluble in hot alcohol, sparingly in cold water and in benzene. Its aqueous solution has a neutral reaction, and, on addition of silver nitrate, yields a silver salt which quickly reduces; the compound is decomposed by acids in the cold, but is very stable towards alkalis; it reduces Fehling's solution in the cold.

Dimethylazietane, $\begin{array}{c} \text{MeC}=\text{N} \\ | \\ \text{N} \\ | \\ \text{MeC}=\text{N} \end{array}$, is obtained when hydrazine hydrate acts on diacetyl in molecular proportion, and is of interest as the first example of a compound formed by the condensation of 1 mol. of hydrazine with two ketonic groups. It separates from boiling benzene as a dull-yellow, microscopic powder, melts at 270°, and is sparingly soluble in boiling alcohol and benzene, and almost insoluble in water; it becomes electrical when rubbed.

Benzoylphenylhydrazimethylene, $\begin{array}{c} \text{HN} \\ | \\ \text{HN} \end{array} > \text{CPh}\cdot\text{COPh}$, is formed from hydrazine hydrate and benzile in molecular proportion; hydrazine hydrate (6 grams) is added to a hot alcoholic solution of benzile (20 grams), and the mixture boiled for some minutes. The product (20 grams) is collected and washed with alcohol; it forms white, crystalline scales, melts at 151° with decomposition, and is sparingly soluble in cold water, easily in hot alcohol. When distilled under a pressure of 30 mm., it boils at 220°, and yields a distillate solidifying to a crystalline mass, which was identified as phenyl benzyl ketone (deoxybenzoin).

Benzoylisobenzaldazine, $\text{CHPh} \begin{array}{c} \text{N} \\ \diagup \quad \diagdown \\ \text{N} \end{array} > \text{CPh}\cdot\text{COPh}$, is produced when benzaldehyde is heated with twice its weight of benzoylphenylhydrazimethylene on the water-bath for a short time; the viscid product soon becomes crystalline, and is spread on a tile, and crystallised from benzene, when it is obtained in large, nodular aggregates; it is deposited from boiling alcohol in small, yellow, lustrous prisms, melts at 150°, and boils with decomposition at 300° under a pressure

of 80 mm. It is insoluble in water, sparingly soluble in boiling alcohol, and easily in boiling benzene.

When a mixture of benzoylisobenzaldazine (10 grams) and hydrazine hydrate (2 grams; 1 mol.), moistened with alcohol, is heated in a sealed tube for 4—5 hours, white needles melting at 131—139°, and a clear oil having an odour recalling that of soap-lye, are obtained; the former, on repeated crystallisation from boiling benzene, yields benzoylphenylhydrazimethylene, and a compound melting at 147° which is perhaps diphenylbihydrazimethylene; the formation of toluene on oxidation was not, however, observed with this (see below); whilst the oil, which contains the benzalhydrazine

on boiling for a short time with cinnamaldehyde, is converted into *cinnamalbenzaldazine*, $\text{CHPh}\cdot\text{N}_2\cdot\text{CH}\cdot\text{CH}\cdot\text{CHPh}$; this crystallises from alcohol in yellow needles and melts at 114°. The benzalhydrazine is a very unstable compound, and decomposes in the presence of water even in the cold into benzaldazine and hydrazine, thus:—

The action of hydrazine hydrate on benzoylisobenzaldazine is therefore probably represented thus:—

Benzoylphenylazomethylene, $\begin{array}{c} \text{N} \\ | \\ \text{N} \end{array}\text{CPh}\cdot\text{COPh}$, is formed when benzoylphenylhydrazimethylene is suspended in benzene and shaken for half an hour with the calculated quantity of mercuric oxide; the orange solution is decanted from the mercury, evaporated, and the compound crystallised from ether, when it is obtained in orange-red, transparent tablets; the yield is quantitative; it melts at 63° with decomposition, and also decomposes when boiled with water or when treated in the cold with mineral acids or an alcoholic solution of iodine.

Diphenylbihydrazimethylene, $\begin{array}{c} \text{HN} \\ | \\ \text{HN} \end{array}\text{CPh}\cdot\text{CPh}\begin{array}{c} \text{NH} \\ | \\ \text{NH} \end{array}$, is prepared by heating benzile (5 grams) with hydrazine hydrate (3 grams) in a sealed tube at 100° for 10 hours. The product crystallises from alcohol in long, colourless needles, melts at 147°, and decomposes at 190°; it remains unaltered on exposure to the air or light, but is decomposed by acids in the cold. When boiled with acetic anhydride, it yields a colourless powder which melts at 238°.

Asymmetrical dibenzylazine, $\text{CH}_2\text{Ph}\cdot\text{CPh}\cdot\text{N}\cdot\text{N}\cdot\text{CPh}\cdot\text{CH}_2\text{Ph}$, is obtained when diphenylbihydrazimethylene is heated for 12 hours at 200° under reduced pressure; on adding alcohol to the greenish, oily product, a yellow powder separates; this is collected, washed with alcohol, and crystallised from boiling alcohol, when it forms lustrous, yellow

needles which melt at 161—162°. It is sparingly soluble in boiling alcohol, readily in benzene, and insoluble in boiling water. The compound gives a white precipitate with silver nitrate, and it is not attacked when its solution in benzene is boiled with mercuric oxide. When dibenzylazine is boiled with sulphuric acid, it is hydrolysed, phenyl benzyl ketone passing over with the steam, whilst hydrazine sulphate remains behind. When diphenylbihydrazimethylene is suspended in benzene and treated with mercuric oxide, it yields toluene, thus:—

A. R. L.

Action of Hydrazine Hydrate on Benzophenone. By T. CURTIUS and F. RAUFERBERG (*J. pr. Chem.* [2], 44, 192—207).—The compound obtained from hydrazine hydrate and benzophenone exhibits no analogy to the derivatives prepared by Curtius and Thun from other ketones (preceding abstract); the authors conclude from its general reactions that it contains the group N·NH (see below).

Diphenylmethylenehydrazine, $\text{CPh}_2\text{N}\cdot\text{NH}_2$, is obtained by heating hydrazine hydrate (1·8 grams) with benzophenone (5 grams) and absolute alcohol (1 gram) in a sealed tube at 150° for six hours, and crystallising from a little alcohol; the yield is almost quantitative. It forms stout prisms several centimetres in length, melts at 98°, and boils undecomposed at 225—230° under a pressure of 55 mm. It is insoluble in water and in alkalis, but readily soluble in ether, benzene, hot alcohol, dilute sulphuric acid, and glacial acetic acid; on adding an alkali to its solution in acids, it is reprecipitated. It yields a metallic mirror when heated with alcoholic silver solution, but only produces a slight reduction with Fehling's solution; after being heated with dilute sulphuric acid, however, the latter is immediately reduced. The molecular weight determinations by Raoult's method, employing benzene as solvent, gave a mean value of 181·8. When the base is mixed with an excess of dilute sulphuric acid and steam distilled, ether extracts benzophenone from the distillate, whilst hydrazine sulphate can be obtained from the residue. The *hydrochloride*, $\text{CPh}_2\text{N}_2\text{H}_2\cdot\text{HCl}$, may be prepared by passing dry hydrogen chloride into an ethereal solution of the base; it forms white needles, melts at 183°, and is very readily soluble in water; it decomposes in aqueous solution, or in the dry state when exposed to the air, yielding bidiphenylazimethylene (see below); the *nitrite*, obtained by passing nitrous acid into an ethereal solution of the base, decomposes in a manner similar to the hydrochloride. The *acetyl derivative*, $\text{CPh}_2\text{N}\cdot\text{NHAc}$, prepared by treating the base (2 grams) with acetic anhydride (0·8 gram), separates from ether in white prisms, melts at 107°, and is easily soluble in alcohol, ether, and benzene; it is not attacked when its benzene solution is boiled with mercuric oxide, and the compound remains unaltered when heated with acetic anhydride at 150°. The *benzoyl derivative*, $\text{CPh}_2\text{N}\cdot\text{NHBz}$, obtained by gently heating the base with benzoic chloride, crystallises in colourless prisms, melts at 116·5°, and is readily soluble in alcohol and ether.

Bidiphenylazimethylene or *diphenylketazine*, $\text{CPh}_2\cdot\text{N}\cdot\text{N}\cdot\text{CPh}_2$, is best prepared by treating diphenylmethylenehydrazine (3 grams) with a solution of iodine (2 grams) in alcohol (10 grams), washing the product with alcohol, and crystallising two or three times from absolute alcohol. It forms small, bright yellow, transparent prisms, melts at 162° , distils undecomposed, and is somewhat sparingly soluble in boiling alcohol, more readily in ether and benzene, but insoluble in alkalis and ammonia. Molecular weight determinations by Raoult's method, employing benzene as solvent, gave a mean value of 317.9. When boiled with dilute sulphuric acid for three hours, the compound dissolves, and on steam distilling the solution, benzophenone passes over, whilst hydrazine sulphate remains in the residue. Bidiphenylazimethylene is also formed when diphenylmethylenehydrazine is distilled under diminished pressure. $2\text{CPh}_2\cdot\text{N}\cdot\text{NH}_2 = \text{CPh}_2\cdot\text{N}\cdot\text{N}\cdot\text{CPh}_2 + \text{N}_2\text{H}_4$ (see also below).

Diphenylmethylenetetrazone, $\text{CPh}_2\cdot\text{N}\cdot\text{N}\cdot\text{N}\cdot\text{N}\cdot\text{CPh}_2$, is obtained by allowing a cooled solution of diphenylmethylenehydrazine to remain in contact with somewhat more than the calculated quantity of mercuric oxide for 24 hours, shaking at intervals. The solution, which first acquires a yellow colour and then becomes red, is quickly evaporated to dryness by a current of air; the residual deep-red oil solidifies to a mass of needles when cooled. The compound, which melts at the temperature of the room, is readily soluble in alcohol, ether, and benzene. On exposure to the air for several days, either by itself or in benzene solution, it decomposes into diphenylketazine and nitrogen; this decomposition is effected in a few hours when the benzene solution is boiled. Diphenylketazine is likewise produced when the tetrazone is treated with iodine, bromine, or hydrogen chloride in an indifferent solvent. If, however, a benzene solution of the tetrazone is treated with hydrogen bromide, diphenylketazine separates and is removed, whilst the filtrate on evaporation in a vacuum yields an oil which soon solidifies; this, after crystallisation from ether, forms colourless prisms, melts at 38° , and is readily soluble in benzene, ether, and alcohol; it was proved to be diphenylbromomethane, which, according to Friedel and Balsohn (Abstr., 1880, 558), melts at 45° .

Diphenylmethylenebenzaldazine, $\text{CPh}_2\cdot\text{N}\cdot\text{N}\cdot\text{CHPh}$, is formed with development of heat when diphenylmethylenehydrazine (2 grams) and benzaldehyde (1.1 grams) are mixed, or better when the two are shaken together in molecular proportion in the presence of a few drops of alkali; it crystallises from alcohol in tufts of sulphur-yellow needles, melts at 75° with partial decomposition, and is readily soluble in ether and alcohol, but insoluble in water. *Diphenylmethylenecinnamaldazine*, $\text{CPh}_2\cdot\text{N}\cdot\text{N}\cdot\text{CH}\cdot\text{CH}\cdot\text{CHPh}$, is prepared in the same manner from diphenylmethylenehydrazine and cinnamaldehyde; it forms lemon-yellow needles, melts at 98° , and is readily soluble in alcohol, ether, and benzene. Diphenylmethylenehydrazine and chloral react with formation of diphenylketazine.

Diphenyldimethylazimethylene, $\text{CPh}_2\cdot\text{N}\cdot\text{N}\cdot\text{CMe}_2$, is obtained on heating diphenylmethylenehydrazine (3 grams) with acetone (1 gram) for an hour on the water-bath in a reflux apparatus; the oily product solidifies, and on being crystallised from ether forms yellowish-green

crystals, melts at 60.5° , is readily soluble in alcohol, ether, and benzene, and remains unaltered when its solution in benzene is boiled with mercuric oxide.

Diphenylmethylcinnamaldazimethylene, $\text{CPh}_2\cdot\text{N}\cdot\text{N}\cdot\text{CMe}\cdot\text{CH}\cdot\text{CHPh}$, is formed from diphenylmethylenehydrazine and benzylideneacetone; it separates from ether in yellow prisms, melts at 126° , and is readily soluble in alcohol, but insoluble in water.

Diphenylmethylphenylazimethylene, $\text{CPh}_2\cdot\text{N}\cdot\text{N}\cdot\text{CMePh}$, is prepared by heating diphenylmethylenehydrazine with acetophenone in a sealed tube at 160° for six hours; it crystallises from alcohol in lustrous, golden-yellow prisms, melts at 105° , distils without decomposition, and is readily soluble in ether, alcohol, and benzene. Bidiphenylazimethylene (diphenylketazine), $\text{CPh}_2\cdot\text{N}\cdot\text{N}\cdot\text{CPh}_2$ (see above), is formed when diphenylmethylenehydrazine and benzophenone are heated together in molecular proportion in a sealed tube at 150° .

A. R. L.

Action of Hydrazine Hydrate on Isatin and Phenols. By T. CURTIUS and K. THUN (*J. pr. Chem.* [2], 44, 187—191).—*Hydrazisatin*, $\text{N}\begin{smallmatrix} \text{C}(\text{OH}) \\ \text{C}_6\text{H}_5 \end{smallmatrix} \begin{smallmatrix} \text{NH} \\ \text{NH} \end{smallmatrix} \text{C}$, is obtained when isatin (20 grams) is

dissolved in hot absolute alcohol (200° c.c.), hydrazine hydrate (7 grams) added, and the mixture boiled for an hour. When cold, the product is collected, washed with alcohol, and recrystallised from the same solvent. It separates from boiling water in pale-yellow needles, or from boiling alcohol in dull, straw-yellow plates, melts at 219° , and is very sparingly soluble in boiling water, alcohol, ether, and benzene. It behaves both as an acid and a base. On adding silver nitrate to its ammoniacal solution, a red salt separates which darkens quickly, but on boiling its aqueous solution with silver nitrate, a metallic mirror is produced. It is decomposed by boiling with mineral acids, and its solution in sodium hydroxide gives a yellow precipitate with Fehling's solution. When hydrazisatin is distilled under a pressure of 90 mm., it boils at 255° , and oxindole passes over; the yield after redistilling under a pressure of 73 mm. (b. p. 227°) is 60 per cent. When a solution of hydrazisatin in benzene is boiled with mercuric oxide, an *azo-derivative* is obtained as a brownish-red powder which deflagrates on heating.

Phenoldiammonium, $\text{N}_2\text{H}_4\text{Ph}\cdot\text{OH}$ (?), is formed when hydrazine hydrate is poured over dry phenol; it melts at $55\text{--}57^{\circ}$, but decomposes even when dried in the desiccator, and could not therefore be analysed.

Hydrazine hydrate acts with explosive violence on quinone with the formation of quinol, which then becomes converted into quinoldiammonium.

Quinoldiammonium, $\text{N}_2\text{H}_4\text{C}_6\text{H}_4(\text{OH})_2$, is precipitated in white plates when hydrazine hydrate (3 grams) is slowly added to quinol (3.5 grams) dissolved in ether. It is collected, washed with ether, and crystallised from boiling alcohol; it separates in thick, white crystals, melts at 154° with decomposition, and is readily soluble in water (the yield is 6 grams). It is very unstable, and decomposes after keeping for some months; it reduces Fehling's solution in the cold,

and when its aqueous solution is shaken with benzaldehyde, benzaldazine is produced.

A. R. L.

Action of Phenylhydrazine on the Benzaldoximes. By G. MINUNNI and L. CABERTI (*Gazzetta*, 21, 136—142).—When either α - or β -benzaldoxime is heated at a little above 100° for some hours with an equal weight of phenylhydrazine, the hydrazone obtained is identical with that prepared by E. Fischer by the direct action of phenylhydrazine on benzaldehyde, and melts at 156 — 157° , and not at 152.5° as stated by Fischer. The lower melting point is caused by the presence of impurity.

In view of Minunni's explanation of the isomerism of the benzaldoximes (this vol., p. 1354), it is supposed that two isomeric hydrazones are initially formed from the isomeric oximes, but that the

β -hydrazone, to which the constitution $\text{NHPh}\cdot\text{N} < \begin{smallmatrix} \text{C}_6\text{H}_5 \\ | \\ \text{CH} \end{smallmatrix}$ is assigned,

undergoes intramolecular change at the moment of formation, and is converted into the stable α -hydrazone, $\text{NHPh}\cdot\text{N}:\text{CHPh}$.

A further investigation of this reaction is being carried on.

W. J. P.

Nitrohalogenhydrazo- and Nitrosohalogenazo-compounds. By C. WILLGERODT and L. ELLON (*J. pr. Chem.* [2], 44, 67—77).—Orthonitroallometachlorophenyl-phenylhydrazine,

is best prepared by boiling an alcoholic solution of Laubenheimer's dinitrochlorobenzene (9 grams) and phenylhydrazine (9.6 grams), and afterwards allowing it to remain in the cold for 24 hours (Willgerodt and Ferko, *Abstr.*, 1888, 830). When reduced by boiling with alcoholic ammonium sulphide for two days, or by boiling with acetic acid, it is converted into orthonitrosoallometachlorophenylazobenzene, melting at 142.5° , not at 136 — 137° as previously stated (*loc. cit.*). On treatment with the calculated quantity of bromine in chloroform solution (10 grams of bromine in 100 c.c. of the solution) at the boiling point for three hours, it yields orthonitrosoallometachlorodibromophenylazobenzene, $\text{C}_{12}\text{H}_5\text{ClBr}_2\text{N}_2\cdot\text{NO}$, which crystallises in lustrous, red needles melting at 143 — 144° . When oxidised with chromic acid in acetic acid solution, the hydrazine is readily converted into orthonitroallometachlorazobenzene, which, on boiling with twice its weight of nitric acid (sp. gr. = 1.48) for 10—12 hours in a reflux apparatus, yields dinitrochlorazobenzene, $\text{C}_{12}\text{H}_7\text{ClN}_2(\text{NO}_2)_2$, crystallising in red needles melting at 75° , and on boiling with six times its weight of a mixture of fuming nitric acid and concentrated sulphuric acid in equal proportions, yields trinitrochlorazobenzene, $\text{C}_{12}\text{H}_4\text{ClN}_2(\text{NO}_2)_3$, melting at 121° .

Picrylparabromophenylhydrazine, $\text{C}_6\text{H}_4\text{Br}\cdot\text{NH}\cdot\text{NH}\cdot\text{C}_6\text{H}_2(\text{NO}_2)_3$, is formed when an alcoholic solution of parabromophenylhydrazine (2 mols.) and picryl chloride (1 mol.) is heated to the boiling point. It crystallises in beautiful, yellowish-red, hexagonal forms, melts at 185 — 186° , and is soluble in almost all organic solvents. When boiled with acetic acid for many hours in a reflux apparatus, it is reduced

to dinitronitrosophenylparabromazobenzene (Willgerodt, this vol., p. 689), and when heated with alcohol at 130—140° for three hours, it is further reduced to *dinitroso nitrophenylparabromazobenzene*, $C_6H_4Br \cdot N_2 \cdot C_6H_3(NO)_2 \cdot NO_2$, which crystallises in yellow needles melting at 241°. On oxidation with chromic acid, the hydrazine is converted into trinitrophenylparabromazobenzene, a compound already prepared by the bromination of picrylphenylhydrazine.

Orthoparadinitrophenylparabromophenylhydrazine,

is obtained by boiling an alcoholic solution of α -dinitrochlorobenzene (5 grams) with parabromophenylhydrazine (10 grams) in a reflux apparatus for some hours. It crystallises in small, dark-brown needles, melts at 147—148°, and dissolves in hot benzene, but only sparingly in other organic solvents. When boiled with acetic acid for about five hours, it is reduced to *nitronitrosophenylparabromazobenzene*, $C_6H_4Br \cdot N_2 \cdot C_6H_3(NO) \cdot NO_2$, crystallising in yellow needles, which melt at 242°. When heated with alcohol at 150° for three hours, it is further reduced to *dinitroso phenylparabromazobenzene*,

this crystallises in yellowish-brown needles, melts at 222°, and is easily soluble in the ordinary organic solvents. On oxidation with chromic acid in acetic acid solution, the hydrazine is converted into *orthoparadinitrophenylparabromazobenzene*, $C_6H_4Br \cdot N_2 \cdot C_6H_3(NO_2)_2$, which crystallises in slender red needles, melts at 175°, and dissolves readily in the ordinary organic solvents.

Orthonitrosoallometachlorophenylazobenzene is not affected by boiling either with alkaline potassium ferricyanide for 8 hours, or with a solution of chromic acid in acetic acid. A compound of the same composition, $C_{12}H_8ClN_3O$, but melting at 121°, is obtained when it is boiled for 8 hours with dilute nitric acid (sp. gr. = 1.12).

Dinitronitrosophenylparabromazobenzene, when boiled with chromic acid in acetic acid solution for about an hour, is oxidised to *dinitro nitrosophenylparabromazoxybenzene*, $O < \begin{matrix} N \cdot C_6H_4Br \\ N \cdot C_6H_3(NO_2)_2 \cdot NO \end{matrix}$, melting at 170.5°.

Dinitroso nitrophenylparabromazobenzene under like conditions is oxidised to *dinitroso nitrophenylparabromazoxybenzene*, $C_{12}H_8BrN_6O_8$, melting at 219°.

When dinitrosophenylparabromazobenzene is boiled with a solution of chromic acid in acetic acid solution for two hours, it yields *dinitrosophenylparabromazoxybenzene*, $C_{12}H_7BrN_4O_8$, melting at 202°.

W. P. W. .

α -Metaxylylhydrazine. By A. KLAUBER (*Monatsh.*, 12, 211—220; compare Abstr., 1890, 1410).— α -Metaxylylhydrazine is deposited from its aqueous solution on the addition of supersaturated brine; it does not yield a crystalline compound with carbon bisulphide, and explodes when heated in a vacuum; on exposing a benzene solution of the hydrazine to the atmosphere, a characteristic deep-green coloration is pro-

duced, which may serve as a qualitative test. The *hydrochloride* crystallises with 2 mols. H_2O in small, colourless needles, which rapidly become brown on exposure to air.

The hydrazine combines with 2 mols. of ethyl acetoacetate when the two are heated together for an hour at $110-120^\circ$, and then for two hours at $140-150^\circ$. The product, which has the formula $C_{22}H_{34}N_4O_4$, is deposited from alcohol in small crystals, and melts at 203° . It dissolves sparingly in xylene or alcohol, is insoluble in water, ether, and benzene, and does not react with phosphorus pentachloride when heated with it at 180° . With acids, it forms salts which are dissociated on the addition of water.

α -*Metaxylylmethylpyrazolone*, C_8H_9N $\begin{smallmatrix} \text{CO}\cdot\text{CH}_2 \\ \text{N}:\text{CMe} \end{smallmatrix}$, is obtained by treating the preceding compound with sodium in alcoholic solution, or by heating it with dilute alkalis or acids at $140-150^\circ$ for two hours in a sealed tube. It crystallises from water containing sodium chloride in concentric needles which melt at 159° . The pyrazolone resembles the corresponding compound from phenylhydrazine, and forms salts with both acids and bases; with ferric chloride, a violet-red coloration is obtained, whilst alkaline copper solutions are readily reduced. The *hydrochloride* is deposited in nodules consisting of prismatic crystals; it melts at 185° . The *ferrocyanide* is sparingly soluble, and quickly undergoes decomposition when heated. On heating the above described condensation product of metaxylylhydrazine and ethyl acetoacetate for two hours at 130° with hydrogen chloride or methyl iodide in methyl alcoholic solution in a sealed tube, α -*metaxylyl-2-3-dimethylpyrazolone* (*xylylantipyrine*), C_8H_9N $\begin{smallmatrix} \text{CO}-\text{CH} \\ \text{NMe}\cdot\text{CMe} \end{smallmatrix}$, is produced. After purification, it crystallises from light petroleum in small, colourless needles, and melts at 113° . It is readily soluble in alcohol, ether, and benzene, and also in cold water, but on heating an aqueous solution the compound separates as a viscid liquid. The *hydrochloride* crystallises with 2 mols. H_2O in long prisms, which decompose at 112° ; the anhydrous salt melts at 95° .

By the action of alkaline nitrites on the hydrochloride, the *nitroso-derivative*, C_8H_9N $\begin{smallmatrix} \text{CO}-\text{C}\cdot\text{NO} \\ \text{NMe}\cdot\text{CMe} \end{smallmatrix}$, is formed; this crystallises from a mixture of alcohol and ether in lustrous, green, metallic needles. The compound has basic properties, and dissolves in acids, but is precipitated from these solutions on the addition of alkalis.

J. B. T.

Behaviour of Aldehydes with Orthamidophenols. By G. MAZZARA and A. LEONARDI (*Gazzetta*, 21, 251-256).—*Benzileamido-*

benzamidothymol, $CH_3\text{Ph}\cdot\text{NH}$  CPh , is prepared by heating

benzaldehyde (8 grams) with diamidothymol hydrochloride in an

oil-bath for 10 hours. The reaction commences below 100° with evolution of hydrogen chloride, and is completed on raising the temperature to 120—130°. The product, after purification and repeated recrystallisation from boiling alcohol, separates in long, silky, yellowish-white needles, and melts at 152°. The base also crystallises from light petroleum in small, yellow rhombohedra. It is very soluble in benzene, forming a feebly fluorescent solution. It is insoluble in alkaline hydrates and dilute acids, and is not decomposed by them even on heating. The *hydrochloride* crystallises from hot alcohol in brilliant, white scales, very sparingly soluble in boiling water. The same compound is obtained by heating amidobenzamidothymol with benzoic chloride. The formation of this benzilebenzenyl derivative leads the author to conclude that the reaction between aldehydes and diamido-derivatives of aromatic hydrocarbons takes place in the following stages:—

With the fatty aldehydes, the reaction is limited for the most part to the second stage. S. B. A. A.

Oxidation of Mixed Fatty Aromatic Ketones by Potassium Permanganate. By A. CLAUS and W. NEUKRANZ (*J. pr. Chem.* [2], 44, 77—85)—Contrary to the experience of Claus (Abstr., 1890, 769), Glücksmann has shown (Abstr., 1890, 1416) that acetophenone can be oxidised by potassium permanganate with the production of phenylglyoxylic acid if an alkaline solution is employed. The conjecture of Glücksmann that the failure to oxidise the ketone was due to the use of a neutral solution is erroneous, since not only neutral but acid and alkaline solutions were employed, and the oxidation in the presence of alkali was conducted, both in concentrated and dilute aqueous solutions, hot, cold, and at intermediate temperatures. Claus, however, always added the whole quantity of alkali to the ketone prior to the addition of the potassium permanganate, whereas Glücksmann rendered the solution of permanganate alkaline, and treated the ketone with successive quantities of the mixture. The authors find that the difference in the two results is to be referred to this slight difference in procedure, and quote experimental data showing that the quantity of alkali within certain limits, like the concentration and temperature of the solution, is of subsidiary importance compared with the manner in which it is added; they conclude therefore that under Glücksmann's conditions, and no others, is it possible to oxidise acetophenone by potassium permanganate.

Paratolyl methyl ketone, on oxidation at 70° with a solution containing 12 grams of caustic potash and 32 grams of potassium permanganate in 200 c.c. of water, yields 70 per cent. of the theoretical

quantity of paratolylglyoxylic acid. This ketone is more readily oxidised to the ketonecarboxylic acid than acetophenone, and small quantities of paratolylglyoxylic acid are even formed when the old method of oxidation in an ice-bath is employed, and the whole quantity of alkali added prior to the addition of the permanganate solution. Orthoxylyl methyl ketone and orthocymyl methyl ketone also yield α -ketonecarboxylic acids on oxidation with potassium permanganate by Glücksmann's method, but details are reserved for a later communication.

Glücksmann's method of oxidation has been applied in the case of ketones which yield α -ketonecarboxylic acids under the old conditions, but experiments with naphthyl methyl ketone, and with mixed aromatic ethyl, propyl, and isopropyl ketones show that neither the nature nor yield of the respective products is altered thereby.

W. P. W.

Paratolylacetic Acid. By A. CLAUS and R. WEHR (*J. pr. Chem.* [2], 44, 85—95).—Paratolylacetic acid is best prepared from paratolyl methyl ketone by Willgerodt's reaction (*Abstr.*, 1888, 476). The ketone is heated with an excess of saturated ammonium sulphide and about 40 per cent. of its weight of powdered sulphur at 250° for 5—6 hours, and the resulting paratolylacetamide boiled with an equal weight of caustic potash and 10—20 times its weight of water for 6—8 hours until ammonia is no longer evolved; the acid is then precipitated in slender, colourless needles on the addition of a mineral acid to the solution. It sublimes in needles without decomposition, melts at 92° (uncorr.), and is easily soluble in alcohol, ether, chloroform, and hot water, but only sparingly in cold water. The lower melting point of 74° previously given (Claus and Kroseberg, *Abstr.*, 1887, 949) was obtained with an impure material, which, on subsequent purification, has been found to melt at 91°. On oxidation with boiling dilute nitric acid (sp. gr. = 1.15), it yields paratoluic acid; with concentrated nitric acid, a mixture of terephthalic acid with nitro-derivatives; and with either chromic acid or potassium permanganate in quantity corresponding with three atomic proportions of oxygen, a mixture of paratoluic acid with a small amount of terephthalic acid.

Metanitroparatolylacetic acid, $\text{NO}_2 \cdot \text{C}_6\text{H}_4 \cdot \text{Me} \cdot \text{CH}_2 \cdot \text{COOH}$, is obtained when a solution of paratolylacetic acid in five times its weight of nitric acid (sp. gr. = 1.52) is allowed to remain in the cold for 14—21 days. It crystallises from water in colourless, transparent, glassy needles, sublimes in small, colourless needles, melts at 102°, and dissolves very sparingly in cold water, but easily in alcohol, ether, carbon bisulphide, &c. On oxidation in alkaline solution with an amount of potassium permanganate corresponding with three atomic proportions of oxygen, it is converted into metanitroparatoluic acid. The *sodium* salt, with $2\frac{1}{2}$ mols. H_2O , crystallises in small, flat needles, and is very soluble in water; the *barium* salt, with 2 mols. H_2O , is less soluble in water, and crystallises in crusts of small needles; the *silver* and *cobalt* salts are also described.

Dimetanitroparatolylacetic acid, $\text{C}_6\text{H}_4 \cdot \text{Me}(\text{NO}_2)_2 \cdot \text{CH}_2 \cdot \text{COOH}$

$[\text{CH}_2 \cdot \text{COOH} : \text{NO}_2 : \text{Me} : \text{NO}_2 = 1 : 3 : 4 : 5]$,

is formed when paratolylacetic acid is added in small quantities to five times its weight of a mixture of fuming nitric acid with twice its weight of pure sulphuric acid cooled below 0° in a freezing mixture. It crystallises from water or dilute alcohol in colourless, silky needles, melts at 158° (uncorr.), and is less soluble than the nitro-acid in boiling water, but equally soluble in alcohol, ether, &c. On oxidation with the calculated quantity of potassium permanganate, it yields dimetanitroparatoluic acid. The *sodium* salt, with 5 mols. H_2O , crystallises in colourless, flat needles, and is less soluble in hot or cold water than the sodium salt of the nitro-acid; the *calcium* salt crystallises in anhydrous, sparingly soluble, colourless prisms.

Paratolylbromacetic acid, $C_6H_4Me-CHBr-COOH$, is obtained when paratolylacetic acid, dissolved in a small quantity of acetic acid, is mixed with the calculated quantity of bromine and 30 times its weight of water and exposed to direct sunlight for some days. It crystallises from water in colourless, short needles, and melts at 125° (uncorr.); it is very sparingly soluble in cold water, but readily in alcohol, ether, chloroform, benzene, and acetic acid. The *barium* salt, with 3 mols. H_2O , crystallises in small, colourless, lustrous scales, and is easily soluble in hot water, but only sparingly in the cold.

Paratolylacetamide crystallises from concentrated aqueous solutions in nacreous scales, from dilute solutions in long, white needles, and melts at 185° .

W. P. W.

Bismuth Salicylate. By H. CAUSSE (*Compt. rend.*, 112, 1220—1223).—The preparation of bismuth salicylate is a matter of some difficulty, because water decomposes the bismuth salts, whilst acids decompose the salicylates. Ammonium salts, however, especially ammonium chloride, tend to prevent the decomposition of the bismuth salts by water, although they have practically no solvent action on the basic bismuth salts themselves.

Basic bismuth nitrate, 100 grams, is dissolved in concentrated hydrochloric acid with the aid of heat, and the solution is poured into 1000 c.c. of a saturated solution of ammonium chloride. The free acid is neutralised either by adding more basic nitrate or by adding a solution of ammonia in ammonium chloride solution until a slight permanent precipitate remains after vigorous agitation. A solution of 120 grams of sodium salicylate in 500 c.c. of saturated ammonium chloride solution is then added, and in a short time the liquid is filled with a bulky, crystalline precipitate of bismuth salicylate, which is drained and washed with water until all ammonium chloride is removed. The dried product has the composition $Bi(C_7H_5O_3)_3 + 4H_2O$, resembles quinine in appearance, is insoluble in water, and is decomposed by acids. It is not affected by cold water, but is decomposed by boiling water and also by absolute alcohol, with separation of bismuth oxide. When heated at 50° , salicylic acid slowly sublimes, and at 100° decomposition is complete.

C. H. B.

Catecholcarboxylic Acids. By R. SCHMITT and H. HÄHL (J. pr. Chem. [2], 44, 1—5).—The introduction of one carboxyl radicle into

catechol and resorcinol can be effected, as is known, by heating these phenols with ammonium carbonate or potassium hydrogen carbonate, but further substitution can only be brought about by heating the monocarboxylates with carbonic anhydride under considerable pressure. When the dry sodium salt of catechol is exposed to the action of compressed carbonic anhydride at the ordinary temperature, 2 molecular proportions of the gas enter into reaction with the formation of sodium orthophenylenecarboxylate, which, by prolonged heating in an autoclave with compressed carbonic anhydride at 120–140° yields sodium catecholcarboxylate, and if the heating is continued at 210° for eight hours, sodium catecholdicarboxylate is formed, mixtures of the two acids being obtained at intermediate temperatures. As the monocarboxylic acid dissolves readily in water, in which the dicarboxylic acid is insoluble, the two compounds can be easily separated. The former proves to be identical with Miller's orthodihydroxybenzoic acid (*Annalen*, 220, 116).

Catecholdicarboxylic acid, $C_6H_2(OH)_2(COOH)_2$, crystallises from water in slender, colourless needles, with 1 mol. H_2O , and from alcohol in anhydrous, yellow scales; it melts at 290° with evolution of carbonic anhydride, does not volatilise with steam, and is only sparingly soluble in hot water and chloroform, but more so in alcohol and ether. The solutions exhibit a deep-blue fluorescence, and the aqueous solution is coloured deep indigo-blue by ferric chloride, and yellow by lead acetate. The *sodium* salt, $C_6H_2(OH)_2(COONa)_2 + 2H_2O$, crystallises in concentrically grouped prisms, which show a marked blue fluorescence, and are readily soluble in water but insoluble in alcohol; the *barium* salt forms tufts of sparingly soluble prisms; the *silver* and *lead* salts are also described. The *dimethyl* salt, $C_6H_2(OH)_2(COOMe)_2$, crystallises in slender, colourless needles, melts at 145°, is insoluble in water but volatile with steam, and dissolves readily in alcohol and ether, forming fluorescent solutions; the *diethyl* salt crystallises in colourless, prismatic tables, melts at 89–90°, and resembles the dimethyl salt in solubility and fluorescence.

Of the sodium salts of the three dihydroxybenzenes, that of catechol is the most sensitive to the action of air. When prepared in an indifferent atmosphere, it is a white powder, which dissolves readily in water and can be rendered anhydrous without difficulty, since it may be heated at 220° in a current of hydrogen without decomposition.

W. P. W.

Preparation of Phenoldicarboxylic Acids. By H. HÄHLE (*J. pr. Chem.* [2], 44, 5–14).—It has been shown that unsymmetrical hydroxyisophthalic acid, free from the consecutive acid, is obtained when either basic sodium salicylate or a mixture of that salt with basic potassium salicylate is heated in a current of carbonic anhydride at 300–400°, the entering carboxyl radicle assuming the para-position relatively to the hydroxyl (Ost, this Journ., 1877, ii, 485). The consecutive acid can, however, be prepared if the basic sodium salt of methyl salicylate, in which an alkyl radicle instead of a metal is substituted for the carboxylic hydrogen, is heated with carbonic anhydride under considerable pressure, and in like manner dicarboxylic

acids containing carboxyl in the ortho-position relatively to the hydroxyl may be obtained from meta- and para-hydroxybenzoic acids.

The basic sodium salt of methyl salicylate is formed when oil of wintergreen, dissolved in an equal quantity of 96 per cent. alcohol, and cooled at 0°, is treated with the requisite quantity of titrated aqueous soda, also mixed with an equal quantity of alcohol. After stirring for a short time, the salt very rapidly separates in lustrous, thin, white scales, and can be obtained perfectly dry by thinning the almost solid mass with alcohol and ether, filtering, pressing, and heating at 140° in a vacuum.

Methyl hydrogen hydroxyisophthalate [COOMe:OH:COOH = 1:2:3] is obtained when the perfectly dry basic sodium salt of methyl salicylate is heated with excess of carbonic anhydride in an autoclave at 150° for about 24 hours. The amount of carbonic anhydride taken up in the reaction did not exceed that corresponding with a half molecular proportion under the various conditions employed. The product is extracted with ether to remove the methyl salicylate and methyl orthomethoxybenzoate formed in the reaction, and subsequently heated on a water-bath with dilute hydrochloric acid. The solution is then rendered slightly alkaline with aqueous ammonium carbonate, steam-distilled to remove any methyl salicylate, acidified, extracted with ether, and the ethereal solution repeatedly precipitated by ammonia. The salt crystallises in characteristic stellate groups of flat needles, which, when powdered, become strongly electrified. It melts at 135°, and also when heated under water; it dissolves readily in alcohol or ether, sparingly in cold but readily in hot water, and in aqueous solution shows a marked blue fluorescence. With ferric chloride in aqueous solution, it gives a carmine coloration. The sodium salt, $\text{COOMe} \cdot \text{C}_6\text{H}_3(\text{OH}) \cdot \text{COONa} + \text{H}_2\text{O}$, crystallises in slender, colourless, concentrically-grouped needles, and dissolves readily in water, forming a solution which exhibits a beautiful blue fluorescence. On hydrolysis, it yields consecutive hydroxyisophthalic acid. It is to be noted that Ost's unsymmetrical hydroxyisophthalic acid is always present in the product, although only in very small quantity; the acids can be readily separated by means of the barium salts, since that of the consecutive acid is only sparingly soluble in water, whilst that of the unsymmetrical acid is easily soluble.

When the reaction between the basic sodium salt of methyl salicylate and carbonic anhydride is conducted at 170° or above, the product consists of a mixture of the sodium salt of consecutive hydroxyisophthalic acid with methyl orthomethoxybenzoate owing to the occurrence of the reaction $\text{COOMe} \cdot \text{C}_6\text{H}_3(\text{OH}) \cdot \text{COONa} + \text{ONa} \cdot \text{C}_6\text{H}_4 \cdot \text{COOMe} = \text{OH} \cdot \text{C}_6\text{H}_3(\text{COONa})_2 + \text{OMe} \cdot \text{C}_6\text{H}_4 \cdot \text{COOMe}$. This accounts for the presence of methyl orthomethoxybenzoate in the product formed at lower temperatures, and for the fact that the amount of carbonic anhydride taken up is only one-half that which was anticipated.

Ethyl salicylate, when treated in like manner, yields consecutive isophthalic acid, but the phenyl salt cannot be employed, since it decomposes into phenol and the basic sodium salt of ethyl salicylate on treatment with sodium ethoxide in alcoholic solution.

Sodium ethyl hydroxyisophthalate [$\text{COOEt}:\text{COONa}:\text{OH} = 1:3:4$] is formed quantitatively when the perfectly dry basic sodium salt of ethyl parahydroxybenzoate is heated with carbonic anhydride under pressure at $160\text{--}170^\circ$, one molecular proportion of the gas entering into reaction. It crystallises in beautiful, colourless prisms, and, on treatment with hydrochloric acid, is converted into *ethyl hydrogen hydroxyisophthalate*, which crystallises from alcohol in colourless, monoclinic scales, melts at $194\text{--}195^\circ$, and, on hydrolysis, yields unsymmetrical hydroxyisophthalic acid. The basic sodium salt of methylparahydroxybenzoate under like conditions also yields the unsymmetrical acid.

When the basic sodium salt of ethylmetahydroxybenzoate is heated with carbonic anhydride under pressure at 170° , and after the operation has continued some time, the material, which tends to agglomerate, is powdered and again submitted to the action of the gas, one molecular proportion of the anhydride is taken up with the production of sodium ethyl hydroxyterephthalate, from which hydroxyterephthalic acid can be obtained by hydrolysis. As the chloroterephthalic acid, which can easily be prepared from this acid, readily undergoes reduction with elimination of the chlorine, this would seem to afford the best method of preparing terephthalic acid.

The phenyl salts of the hydroxyisophthalic acids are described since they serve as an additional means of identification. *Phenyl 1:2:3-hydroxyisophthalate* crystallises from alcohol in colourless prisms, and melts at 99° . *Phenyl ethyl 1:3:4-hydroxyisophthalate* [$\text{COOEt}:\text{COOPh}:\text{OH} = 1:3:4$], obtained by heating the ethyl hydrogen salt with phenol and phosphorus oxychloride, crystallises from alcohol in colourless needles, and melts at $64\text{--}65^\circ$.

W. P. W.

Phthalaldehydic Acid. By O. ALLENDORFF (*Ber.*, 24, 2346—2354), —Liebermann (*Abstr.*, 1887, 46) obtained hemipinimide by boiling an alcoholic solution of opianic acid with hydroxylamine hydrochloride, but he afterwards found (*ibid.*, 258) that when the reaction took place at the ordinary temperature, opianoximic anhydride was produced, the latter undergoing an intramolecular change when heated with formation of hemipinimide. Racine (*Annalen*, 239, 81) obtained benzaldoximorthocarboxylic acid by mixing aqueous solutions of phthalaldehydic acid and hydroxylamine hydrochloride, and this acid yielded the anhydride, phthalimide, on heating. The oximic acid is therefore wanting in the hemipinic series, and the corresponding anhydride in the phthalyl series.

Benzaldoximorthocarboxylic anhydride, $\text{CO} < \begin{smallmatrix} \text{O-N} \\ \text{C}_6\text{H}_4 \end{smallmatrix} > \text{CH}$, separates in white crystals when phthalaldehydic acid (4 grams) is dissolved in 80 per cent. alcohol (12 grams) and hydroxylamine hydrochloride (2.2 grams) added with frequent shaking. It slowly dissolves with decomposition in sodium carbonate solution, and on fusion it behaves like opianoximic anhydride (*loc. cit.*) thus:—When quickly heated to 120° , the temperature suddenly rises to 215° with formation of the isomeric phthalimide; whilst if carefully heated in a capillary tube, it

melts at 187° , resolidifies, and then melts again at $225-228^{\circ}$. This is explained as follows: the benzaldoximecarboxylic anhydride is converted at 120° into an isomeride melting at 187° , and this, later on, undergoes intramolecular change into phthalimide, as the temperature is raised. The intermediate compound (m. p. 187°) is obtained when benzaldoximorthocarboxylic anhydride is heated in an oil-bath at 145° , and the product extracted with boiling benzene and crystallised from aqueous acetone. It is distinguished from benzaldoximorthocarboxylic anhydride by its insolubility in benzene, and from phthalimide by its more ready solubility in cold sodium carbonate solution. It is identical with the compound obtained by Kuhara (Abstr., 1881, 1039) from phthalyl chloride and ammonia, and has one of the two formulæ $\text{C}_6\text{H}_4\langle\begin{smallmatrix} \text{C}=\text{O} \\ \text{C}\cdot\text{NH} \end{smallmatrix}\rangle\text{O}$ or $\text{CN}\cdot\text{C}_6\text{H}_4\cdot\text{COOH}$; the second, ortho-

cyanobenzoic acid, being the more probable from the solubility of the compound in sodium carbonate solution. Phthalimide is obtained direct when an alcoholic solution of phthalaldehydic acid and hydroxylamine hydrochloride is boiled in a reflux apparatus for some time. An attempt to prepare opianoximic acid by the action of hydroxylamine hydrochloride on opianic acid in aqueous solution led to a negative result, the anhydride alone being formed.

Diphenylhydrazonophthalaldehydic acid, $\text{C}_6\text{H}_4(\text{CH}\cdot\text{N}\cdot\text{NPh}_2)\cdot\text{COOH}$, is prepared by adding a hot concentrated aqueous solution of asymmetrical diphenylhydrazine hydrochloride (1 mol.) to one of phthalaldehydic acid and sodium acetate in molecular proportion, together with a trace of hydrochloric acid; on boiling the mixture for a short time, a green, resinous precipitate separates, which is purified by crystallisation, first from a small quantity of glacial acetic acid, and then from benzene. It forms lustrous, yellow, truncated prisms, melts at 187° , and is readily soluble in ether, alcohol, acetone, chloroform, and hot benzene, but insoluble in water and light petroleum. The *calcium salt* is a yellow precipitate. The acid, and not the ethyl salt, is formed by the action of diphenylhydrazine hydrochloride on ethyl phthalaldehyde.

Phthalidylhydrazobenzene, $\text{C}_{20}\text{H}_{16}\text{N}_2\text{O}_2$, is formed when hot alcoholic solutions containing hydrazobenzene and phthalaldehydic acid, in molecular proportion, are mixed; the white crystals which separate are obtained as lustrous needles on recrystallisation from absolute alcohol; it darkens at 150° , melts at $202-203^{\circ}$, and is readily soluble in benzene, acetone, and chloroform, less so in alcohol and ether, and insoluble in water and light petroleum. It is not a carboxylic acid, does not contain an aldehyde group, and has probably a constitution analogous to Bistrzycki's opianylhydrazobenzene (Abstr., 1888, 1209), thus: $\text{NHPh}\cdot\text{NPh}\cdot\text{CH}\langle\begin{smallmatrix} \text{C}_6\text{H}_4 \\ \text{O} \end{smallmatrix}\rangle\text{CO}$.

Benzidylphthalaldehydic acid, $\text{C}_{12}\text{H}_8(\text{N}\cdot\text{CH}\cdot\text{C}_6\text{H}_4\cdot\text{COOH})_2$, is obtained when aqueous solutions of phthalaldehydic acid (2 mols.) and benzidine (1 mol.) are boiled together for a short time; it separates as a white, pulverulent precipitate, and may be purified by boiling with absolute alcohol. It is insoluble in the ordinary solvents, but dissolves in boiling nitrobenzene and in cold sodium carbonate solu-

tion; it also dissolves in concentrated sulphuric acid with a yellow coloration, which soon changes to brownish-red. When the *calcium salt* is boiled with water, benzidine is eliminated.

Methylphenylhydrazonophthalaldehydic acid,

is produced when hot concentrated alcoholic solutions containing phthalaldehydic acid and methylphenylhydrazine, in molecular proportion, are mixed and boiled together for a short time. It forms bright-yellow crystals, melts at 167° , and is easily soluble in alcohol, benzene, chloroform, ether, and acetone, but only sparingly in light petroleum, and is insoluble in water.

Allylphenylhydrazonophthalaldehydic acid, $\begin{matrix} \text{PhN} \\ | \\ \text{C}_6\text{H}_5\cdot\text{N} \end{matrix} > \text{CH}\cdot\text{C}_6\text{H}_4\cdot\text{COOH}$,

is obtained by mixing hot concentrated solutions of symmetrical allylphenylhydrazine and phthalaldehydic acid in molecular proportion, and boiling for a short time. It crystallises from alcohol in lustrous, yellow prisms, melts at 160° , and is easily soluble in alcohol, benzene, acetone, chloroform, and dilute solutions of alkali carbonates, sparingly in light petroleum, and is insoluble in water; it dissolves in concentrated sulphuric acid with a red colour.

Acetylphenylhydrazonophthalaldehydic acid, $\begin{matrix} \text{PhN} \\ | \\ \text{AcN} \end{matrix} > \text{CH}\cdot\text{C}_6\text{H}_4\cdot\text{COOH}$, is

formed by boiling together phthalaldehydic acid and acetylphenylhydrazine in molecular proportion. It crystallises from dilute alcohol in small, granular crystals, melts at 191° , and is soluble in alcohol, chloroform, and hot benzene, fairly so in hot water, and almost insoluble in ether and light petroleum; it dissolves slowly in cold solutions of alkali carbonates.

A. R. L.

Action of Potassium Cyanide on Ethyl Opianate. By G. GOLDSCHMIEDT and L. EGGER (*Monatsh.*, 12, 49—80).—In many of its reactions, opianic acid behaves as an aldehydo-orthocarboxylic acid, $\text{COH}\cdot\text{C}_6\text{H}_2(\text{OMe})_2\cdot\text{COOH}$; whilst in others, it resembles the isomeric anhydride (Liebermann, *Abstr.*, 1886, 550, and 1887, 45). The authors consequently expected that the compound, when treated with potassium cyanide, would not behave in the same way as benzaldehyde and anisaldehyde, which give rise to benzoin and anisoïn respectively. This supposition proves to be correct, for when equal weights of perfectly dry ethyl opianate and potassium cyanide are intimately mixed and heated in a reflux apparatus for one hour with 10—12 times their weight of absolute alcohol, *tetramethoxydiphthalyl*, $(\text{OMe})_2\text{H}_2\text{C}=\text{C}=\text{C}=\text{C}_6\text{H}_2(\text{OMe})_2$, a very insoluble compound, is

formed. It crystallises in masses of brilliant, yellow, slender needles, having a beautiful, green fluorescence, which is also shown in chloroform or in acetic acid solution, or, best of all, when the substance is shaken with water. It does not change when heated to 300° ; but above this, it commences to blacken, and only melts when the temperature is further considerably raised. It is almost insoluble

in ordinary solvents; may be sublimed with partial decomposition. It is not changed by cold concentrated potash, but dissolves when warmed with it, forming a yellow solution. A small quantity of the substance imparts an orange-red colour and a strong, yellow fluorescence to concentrated sulphuric acid, and the solution thus obtained becomes claret-coloured on heating, whilst the addition of a small quantity of nitric acid turns it green, indigo-blue, violet, and fiery-red successively.

Tetramethoxydiphthalyl, $C_{16}H_8O_4(OH)_4$, obtained by the action of hydriodic acid on the tetramethoxydiphthalyl, is a greenish-grey powder, which commences to blacken at 300° , without previously melting. It is almost insoluble in alcohol, benzene, carbon bisulphide, and xylene, and only sparingly soluble in acetone, amyl alcohol, and ethyl acetate, crystallising from the last-named solvent in yellow, microscopic needles. With dilute ammonia, it gives an intense dark-green coloration, which becomes of a beautiful lilac on the addition of hydrochloric acid.

Tetramethoxydiphthalyl dicarboxylic acid, $C_{20}O_2[C_6H_3(OMe)_2COOH]_2$ [$COOH : (OMe)_2 : CO = 1 : 4 : 5 : 6$], is obtained when a mixture of tetramethoxydiphthalyl (2 grams) and potash (1 gram) in alcohol (30 grams) is heated in a reflux apparatus. The product of the reaction is a reddish-yellow liquid, which, on dilution with water, evaporation of the alcohol, and addition of hydrochloric acid, furnishes the acid in the form of white, microscopic, rhombic scales. It commences to decompose at 220° and melts at 270° , dissolves readily in alkalis, giving a yellow solution, and reduces ammoniacal silver nitrate when boiled with it. The acid is almost insoluble in water, dissolves readily in acetone, but is best recrystallised from alcohol; the *barium* salt, $C_{20}H_{16}O_{10}Ba + 3H_2O$, forms shining, yellow crystals; the *dihydrasone* is not characteristic. On heating the acid in a flask placed in an oil-bath at 250° , a sublimate of hemipinic acid, melting at 166 — 167° , is obtained, whilst the residue in the flask consists of tetramethoxydiphthalyl. When the acid (1 gram) is fused with solid potash (5 grams), a substance which is most probably methyl-norhemipinic acid (compare Wegscheider, *Monatsh.*, 3, 376) is obtained.

Tetramethylbenzhydroletricarboxylic acid,

is obtained on heating tetramethoxydiphthalyl (2 grams) with a large excess of potash (10 grams) in absolute alcohol (100 grams). It melts at 140° , is soluble in water, alcohol, ether, and acetone, and gives, with concentrated sulphuric acid, a beautiful scarlet coloration. The *barium* salt, $(C_{20}H_{17}O_{11})_2Ba_2 + 5H_2O$, crystallises in slender, silky needles, and is readily soluble in water.

When the alcoholic filtrate obtained after separation of the tetramethoxydiphthalyl from the products of the reaction of potassium cyanide and ethyl opianate is evaporated to a syrupy consistence and allowed to remain over night, a considerable quantity of ethyl hemipinate (m. p. 71°) crystallises out. From the mother liquor, by

cautious addition of hydrochloric acid, a brownish resin is precipitated, and this, on evaporation of its alcoholic solution, gives colourless crystals of *tetramethoxydihydrodiphthalyl*, $C_{20}H_{18}O_8$, melting at 204° . On evaporating the solution from which the resin has separated, an uncrystallisable syrup is obtained having the properties of an acid.

Ethyl hemipinate and tetramethoxydihydrodiphthalyl are formed when an alcoholic solution of potassium cyanide is warmed with tetramethoxydiphthalyl; they must, therefore, be regarded as secondary products in the action of potassium cyanide on ethyl opianate. G. T. M.

Action of Carbonic Chloride on Glycol Chlorhydrins. By P. OTTO (*J. pr. Chem.* [2], 44, 15—23).—By acting on glycol chlorhydrin with carbonic chloride, Nemirowsky (Abstr., 1885, 741) obtained ethyl chlorethylchlorocarbonate, which, by the action of aniline and treatment of the resulting ethyl chlorethylphenylcarbamate with aqueous caustic potash, gave the compound $\begin{matrix} CH_2 \cdot CH_2 \\ | \\ NPh \cdot CO \end{matrix} > O$. The author

finds that if very concentrated aqueous potash is employed, an oil is obtained, which, unlike the anhydride, is soluble in ether and has basic properties. On distillation, the greater part, consisting of hydroxyethylaniline, passes over at 280 — 285° , whilst the residue in the retort crystallises from alcohol in needles, melts at 154° , and is identical with Hofmann's diethylenediphenyldiamine.

Hydroxyethylaniline is best prepared by boiling glycol chlorhydrin (10 grams) with recently distilled aniline (22 grams) in a reflux apparatus for 16 minutes, rendering the product alkaline, and extracting with ether. The yield amounts to 70 per cent. of the theoretical. When a mixture of hydroxyethylaniline with liquid carbonic chloride is kept in a tube for about five hours, a crystalline magma consisting of Nemirowsky's anhydride is obtained. This compound is also formed, together with hydroxyethylaniline hydrochloride, when a current of carbonic chloride is passed into an ethereal solution of hydroxyethylaniline. The anhydride is, moreover, obtained when methylhydroxyethylaniline is treated with carbonic chloride, methyl chloride being eliminated in the condensation.

Ethyl chlorethyl- α -naphthylcarbamate, $CH_2Cl \cdot CH_2 \cdot O \cdot CO \cdot NH \cdot C_{10}H_7$, prepared by treating α -naphthylamine with ethyl chlorethylchlorocarbonate under water, crystallises from alcohol in long, matted needles, melts at 100 — 101° , and is readily soluble in alcohol and ether, but practically insoluble in water. The β -compound forms lustrous scales, melts at 98° , and dissolves readily in alcohol and ether. On treatment with aqueous caustic potash (1 : 2), both substances yield the corresponding anhydrides. The α -compound,

crystallises in scales, melts at 125° , and is insoluble in ether, but readily soluble in hot alcohol; the β -derivative crystallises in prisms,

melts at 189° , and is insoluble in ether, sparingly soluble in hot alcohol. With a saturated caustic potash solution, however, analogues of hydroxyethylaniline are obtained, which dissolve in ether, and on evaporation of the solutions are obtained in the crystalline form. *Hydroxyethyl- α -naphthylamine*, $\text{OH}\cdot\text{CH}_2\cdot\text{CH}_2\cdot\text{NH}\cdot\text{C}_{10}\text{H}_7$, crystallises in needles, melts at 52° , and is very soluble in alcohol and ether. The solutions, on evaporation, leave oily drops, which slowly crystallise with formation of blue needles. The β -compound crystallises in scales, melts at 51° , and is extremely soluble in alcohol and ether. Its *hydrochloride* separates from hot water in lustrous scales, and, unlike the hydrochloride of the α -compound, does not reduce silver solutions.

Ethyl dichlorisopropylchlorocarbonate, $\text{CH}(\text{CH}_2\text{Cl})_2\cdot\text{O}\cdot\text{COCl}$, is formed when α -dichlorhydrin is heated with liquid carbonic chloride at 170° for about 24 hours. It boils at 185 – 187° , and on treatment with aniline and α - and β -naphthylamine, yields a series of compounds which dissolve readily in alcohol and ether, and are converted into the corresponding anhydrides by the action of aqueous caustic potash (1 : 2). *Ethyl dichlorisopropylcarbamate* crystallises in large, seemingly rhombic forms melting at 80° , *ethyl dichlorisopropylphenylcarbamate* in large, seemingly rhombic forms melting at 73° , *ethyl dichlorisopropyl- α -naphthylcarbamate* in lustrous, white needles melting at 115° , whilst *ethyl dichlorisopropyl- β -naphthylcarbamate* forms scales melting at 101° . The anhydrides are readily soluble in alcohol, but insoluble in ether; the anhydride obtained from the phenylcarbamate crystallises in long needles melting at 103° , that from the α -naphthylcarbamate in scales which melt at 118° , and that from the β -naphthylcarbamate in needles melting at 107° .

Ethyl β -dichloropropylchlorocarbonate is obtained when β -dichlorhydrin cooled in ice-cold water is treated with a small excess of carbonic chloride, and the reaction allowed to continue during about six hours, until hydrogen chloride is no longer evolved; it boils at 185 – 187° , and has the odour of ethyl chlorocarbonate. *Ethyl $\alpha\beta$ -dichloropropylcarbamate* crystallises in large, rhombic forms melting at 75° , *ethyl $\alpha\beta$ -dichloropropylphenylcarbamate* in prisms melting at 73 – 74° , *ethyl $\alpha\beta$ -dichloropropyl- α -naphthylcarbamate* in lustrous needles which melt at 93° ; and *ethyl $\alpha\beta$ -dichloropropyl- β -naphthylcarbamate* in scales melting at 99° . These compounds do not react either with dilute (1 : 2) or concentrated aqueous potash. W. P. W.

Paraxylenedisulphonic Acid. By J. H. HOLMES (*Amer. Chem. J.*, 13, 371–384).—*Xylenedisulphonic chloride*, $\text{C}_6\text{H}_4\text{Me}(\text{SO}_2\text{Cl})_2$, was prepared as follows:—Paraxylene (35 grams) was added, with constant shaking, to twice its volume of fuming sulphuric acid diluted with a small quantity of ordinary acid, and the mixture first cooled, but finally warmed. The solution was diluted (4 or 5 litres), neutralised with chalk, filtered, evaporated (2 litres), sodium carbonate added, again filtered, and evaporated to dryness. The sodium xylenesulphonate thus obtained was treated with phosphorus pentachloride (equal weight), the product heated for some time on the water-bath, and much water added, when xylenesulphonic chloride separated as

an oily liquid, which did not entirely solidify in a freezing mixture. This chloride was treated with fuming sulphuric acid as long as a drop of the mixture gave a turbidity when dropped into water; the acids were neutralised with chalk, the sodium salt obtained as above, and treated with twice its weight of phosphorus pentachloride. After evaporating off the phosphorus oxychloride, the xylenedisulphonic chloride was separated by pouring the mixture into several litres of water; it crystallises from light petroleum in white, radiating tufts, and melts at 72–74°. It dissolves easily in cold alcohol, from which, however, it cannot be again obtained; it is soluble also in other organic solvents, but will not crystallise from them.

Xylenedisulphonic acid, $C_6H_4Me_2(SO_3H)_2$, is obtained from the chloride by boiling it with water in a reflux apparatus, evaporating the solution on the water-bath several times, until no more hydrochloric acid is given off, and decolorising with animal charcoal; it crystallises in needles, which are very soluble in water. The *barium*, *calcium* (with 4 mols. H_2O), *lead* (with 3 mols. H_2O), *magnesium* (with 7 mols. H_2O), and *silver* (with 1 mol. H_2O) salts are described; they are very hygroscopic. The authors found that a second preparation of the acid would not crystallise, and gave an amorphous calcium salt; the last three salts mentioned above were made from this preparation. The *amide*, $C_6H_4Me_2(SO_2NH_2)_2$, made by the action of ammonia on the chloride, crystallises from water in microscopic, thin, tabular plates, and from a hot solution in dilute alcohol in very small, satiny crystals, which do not settle, even on long standing. It melts with partial decomposition at 294–295°, and dissolves readily in acetone and pyridine, but only slightly in water, glacial acetic acid, chloroform, or ether. The amide obtained from the uncrystallisable acid was mostly amorphous.

Disulphamineparatoluic acid, $C_6H_4Me(SO_2NH_2)_2COOH + H_2O$, is obtained by oxidising the above amide with alkaline potassium permanganate; it forms ill-defined crystals which melt about 272°; it burns on platinum foil, leaving no residue. The *potassium* (with 2 mols. H_2O), *barium* (with $2\frac{1}{2}$ mols. H_2O), *calcium*, *lead* (with 3 mols. H_2O), and *silver* (with 2 mols. H_2O) salts are described.

The amorphous amide referred to above gave a small quantity of another oxidation product when treated with alkaline permanganate; this formed crystals melting about 274°, but was not further investigated.

The evidence obtained in this investigation is insufficient to settle the orientation of the sulphonic acid groups in this disulphonic acid.

A. G. B.

New Synthesis of Isindazole Derivatives. By K. AUWERS and F. v. MEYENBURG (*Ber.*, 24, 2370–2388).—According to the investigations of E. Fischer and his pupils, indazole and isindazole compounds are derived from the hypothetical substances $C_6H_4<\begin{smallmatrix} CH \\ N- \end{smallmatrix}>NH_2$ and $C_6H_4<\begin{smallmatrix} CH \\ NH \end{smallmatrix}>N$ respectively; the evidence is, on the one hand, the formation of 3'-methylindazole from acetophenoneorthohydrazine-

sulphonic acid, and on the other hand the fact that, with the single exception of the synthesis of nitrophenylisindazolecarboxylic acid (V. Meyer, Abstr., 1889, 516), all the known derivatives of isindazole have been obtained from alkylated amido-derivatives of benzene. Although the formation of isindazole derivatives is *a priori* to be expected when the oximes of aromatic orthamidoketones are treated with dehydrating agents, that of indazole derivatives is not impossible; indeed, on glancing at the above formulæ, it is seen that these only represent desmotropic forms of the same compound, and that true isomerism can only occur when the imidic hydrogen is substituted.

Orthamidacetophenone oxime, $\text{NH}_2\cdot\text{C}_6\text{H}_4\cdot\text{CMe}\cdot\text{NOH}$, is obtained when orthamidacetophenone (1 mol.), hydroxylamine hydrochloride (3 mols.), and potassium hydroxide (8–9 mols.) are digested in alcoholic solution on the water-bath for half an hour. The solution is filtered from potassium chloride, the greater portion of the alcohol evaporated off, and water added; the bulk of the oxime then separates as a white, crystalline mass, the remaining portion being precipitated by a stream of carbonic anhydride. The same oxime is slowly formed by the action of an alkaline solution of hydroxylamine on orthamidacetophenone at the ordinary temperature, or when the ketone is heated with an alcoholic solution of hydroxylamine hydrochloride (3 mols.) at $100\text{--}160^\circ$; at the higher temperature, however, much of the product resinifies. The compound is easily soluble in boiling water, crystallises therefrom in small, delicate, felted needles, and melts at 109° ; it is also readily soluble in alcohol, ether, and benzene, but only sparingly in light petroleum; water containing a few drops of hydrochloric acid dissolves it readily, whilst it is less soluble in concentrated hydrochloric acid. It is very stable when heated, distils with slight decomposition only, and sublimes at the temperature of the water-bath. The *hydrochloride* separates from water in clusters of long, delicate needles. The *diacetyl derivative*, $\text{NHAc}\cdot\text{C}_6\text{H}_4\cdot\text{CMe}\cdot\text{NOAc}$, is prepared by pouring over the oxime twice its weight of acetic anhydride, when it dissolves with development of heat, the new compound separating after a time in iridescent plates; it is completely precipitated on adding water. After crystallisation from 30 per cent. alcohol, it melts at 127° ; it is hydrolysed when left in contact with aqueous sodium hydroxide for 1–2 days.

1' : 3'-*Acetylmethylisindazole*, $\text{C}_{10}\text{H}_{10}\text{N}_2\text{O}$, is best prepared by dissolving the oxime described above (1 part) in a mixture of glacial acetic acid (8 parts) and acetic anhydride (2 parts), saturating the solution, cooled by water, with hydrogen chloride, and allowing it to remain at the ordinary temperature for four days; the yellowish-red liquid is then concentrated on the water-bath to a syrup, and saturated with sodium carbonate. The precipitate is collected and spread on a porous tile; a further quantity may be extracted from the mother liquor by ether. It crystallises from a small quantity of boiling water in delicate, silky, colourless needles, melts at 103° , is readily soluble in all organic solvents, with the exception of light petroleum, but only sparingly in aqueous alkalis. The compound closely resembles E. Fischer's methylindazole, and has the same sweet

taste; it yields a compound with mercuric chloride, crystallising from boiling water in needles. One of its chief characteristics is a tendency to separate out in a delicate, arborescent form, when its solution in a volatile solvent is left to evaporate. In the dry condition it slowly acquires a yellow colour, but when moist it rapidly becomes of an intense red. Its aqueous solution has a strong, green fluorescence, whilst its solution in an alkali resembles an alcoholic solution of chlorophyll. Attempts to prepare isindazole from orthamidobenzophenone oxime and hydrochloric acid led to negative results.

Acetylorthamidacetophenone oxime, $C_{10}H_{13}N_2O_2$, is obtained when a dilute alcoholic solution of acetylorthamidacetophenone (Baeyer and Blöm, Abstr., 1883, 198) (2 grams), hydroxylamine hydrochloride (3 grams), and caustic alkali (2 grams) is heated on the water-bath for 4—5 hours. After purification, it separates from boiling water in colourless, flat needles, and from benzene in lustrous prisms; it melts at 149—150°. When the oxime is treated with a mixture of glacial acetic acid and acetic anhydride, the above-described 1' : 3'-acetylmethylisindazole is formed, thus :—

2' : 3'-Acetylmethylindazole, $C_8H_7 \begin{array}{c} \text{CMe} \\ \text{N} \end{array} \text{NAc}$, is prepared by acetylating E. Fischer's methylindazole (m. p. 113°; *Annalen*, 227, 316); it crystallises from 30 per cent. alcohol in thin plates or long needles, and melts at 72°. When the acetylmethylindazole is heated with aqueous sodium hydroxide for 1—2 hours on the water-bath, methylindazole (m. p. 113°) is obtained; whereas the acetylmethylisindazole, under similar conditions, yields orthamidacetophenone oxime.

Orthamidacetophenone hydrazone, $C_{14}H_{15}N_3$, is obtained in nearly theoretical yield, when orthamidacetophenone is digested in alcoholic solution with an excess of phenylhydrazine acetate for 1—2 hours on the water-bath. It is precipitated by sodium carbonate, and purified by crystallisation from a small quantity of boiling alcohol, with the addition of animal charcoal; it separates in small, delicate needles, melts at 108°, and is readily soluble in boiling water, as well as in most organic solvents, with the exception of light petroleum. The oxime, $C_{13}H_{13}N_2O$, is obtained when orthamidobenzophenone, prepared by Geigy and König's method (Abstr., 1885, 1236), is heated with hydroxylamine and an excess of alkali in dilute alcoholic solution for 4—5 hours on the water-bath. After filtering and driving off most of the alcohol, it is precipitated by a stream of carbonic anhydride, and crystallised from dilute alcohol. It forms small, delicate needles or four-sided plates, melts at 156°, and is readily soluble in most solvents, except cold water and benzene. The yield is only 50—60 per cent. of the theoretical, and is not improved by conducting the experiment at the ordinary temperature; as the melting point only becomes constant after repeated crystallisation, an isomeride (see below) is,

perhaps, simultaneously formed. The *diacetyl derivative*, $C_{11}H_{12}N_2O_2$, melts at 218° , and is sparingly soluble in most solvents; dilute sodium hydroxide decomposes it into the oxime.

1' : 3'-*Acetylphenylisindazole*, $C_6H_4 \begin{smallmatrix} \text{CPh} \\ \text{N} \end{smallmatrix} \text{N}$, is obtained when the amidobenzophenone is allowed to remain for 10 days with a mixture of glacial acetic acid and acetic anhydride. The solution is evaporated, aqueous sodium carbonate added, and the crude substance repeatedly crystallised from dilute alcohol. The compound has all the properties of an indazole derivative; it dissolves readily in most solvents and in hot water, crystallises in small, lustrous plates or needles, and melts at 185° . When digested with dilute sodium hydroxide for 1–2 hours on the water-bath, a compound is obtained having the composition of an *amidobenzophenone oxime*, which melts at 123 – 125° , and yields a *diacetyl derivative*, melting at 218° . The existence of a single amidacetophenone oxime and of two amidobenzophenone oximes is in agreement with the observations of Hantzsch (this vol., p. 36).

Acetylorthamidobenzophenone, $C_{15}H_{13}NO_2$, is formed when orthamidobenzophenone is gently heated with acetic anhydride. It crystallises from dilute alcohol in scales and thick needles, and melts at 72° . Attempts to prepare the oxime were unsuccessful.

Benzenylphenylenediamine (anhydrobenzoyldiamidobenzene), already described by Hübner (Abstr., 1881, 1131), is obtained in almost theoretical yield when an alcoholic solution of orthamidobenzophenone (1 mol.) and hydroxylamine hydrochloride (3 mols.) is heated at 130 – 140° in a sealed tube for 3–4 hours; its melting point (291°) is higher than that observed by Hübner. The same base is formed in small quantity when orthamidobenzophenone oxime hydrochloride is heated for several hours with alcohol at 150° , or in the presence of a few drops of hydrochloric acid at 130 – 140° . A. R. L.

A New Series of Hydroxynitro-derivatives of Triphenylmethane and its Homologues. By G. BERTONI (*Gazzetta*, 21, 167–174).—The author applies Baeyer's method for the preparation of triphenylmethane derivatives by the action of aromatic aldehydes on phenols to metanitrobenzaldehyde, and in this way has obtained derivatives of orcinol and phloroglucinol.

Metanitrophenyldiorcinolmethane, $CH[C_6H_2Me(OH)_2]_2 \cdot C_6H_4 \cdot NO_2$, is obtained when the theoretical proportions of orcinol and metanitrobenzaldehyde are gently warmed with sulphuric acid ($H_2SO_4 + 2H_2O$). The crude product is purified by continued washing with boiling water, and subsequent precipitation from its alcoholic and ethereal solutions by water and light petroleum respectively. The pure substance is an amorphous powder of the colour of manganese sulphide, and is soluble in alcohol, ether, acetic acid, and alkalis. It darkens slowly on exposure to air and light, and on heating softens at 241° , but does not melt. The position in the orcinol molecules occupied by the central methane carbon atom cannot be fixed with certainty.

Metanitrophenyldiphloroglucinolmethane, $CH[C_6H_2(OH)_3]_2 \cdot C_6H_4 \cdot NO_2$

[OH : OH : CH : OH = 1 : 3 : 4 : 5], is obtained with great readiness by the action of metanitrobenzaldehyde on anhydrous phloroglucinol at about 200°, without any condensing agent; the crude substance is purified in the same way as the preceding compound. It is an amorphous powder, soluble in alcohol, ether, and acetic acid, blackens on heating to 245°, but does not melt, and its ethereal solution darkens rapidly on exposure to air. W. J. P.

Nitro-derivatives of α -Ethoxynaphthalene. By P. HEERMANN (*J. pr. Chem.* [2], 44, 238—245).— *α -Ethoxynitronaphthalene* is obtained, together with an isomeride (see below), when α -ethoxynaphthalene is dissolved in $2\frac{1}{2}$ —3 times its weight of glacial acetic acid, and treated at a temperature not exceeding 20° with $1\frac{1}{2}$ times the theoretical quantity of nitric acid (sp. gr. 1.43). After repeated crystallisation from alcohol, it forms yellow needles; it melts at 116—117°, is volatile with steam, and is soluble in most organic solvents. The yield is 90 per cent. of the theoretical. When boiled with alcoholic potash, it is converted into the corresponding nitronaphthol (m. p. 164°), and into the nitronaphthylamine (m. p. 191°) when heated with alcoholic ammonia in a sealed tube at 180°.

$\alpha\beta$ -Ethoxynitronaphthalene is precipitated on adding water to the glacial acetic acid and alcoholic mother liquors from the $\alpha\alpha$ -derivative. When crystallised from light petroleum, it forms bright-yellow needles, melts at 84°, is volatile with steam, and much more soluble in alcohol than the isomeric compound; the yield is 2—4 per cent. of the total nitration product. On boiling with alcoholic potash, it readily yields the corresponding nitronaphthol melting at 128°, but is not altered when heated for eight hours in a sealed tube at 180—190° with alcoholic ammonia.

$\alpha\alpha\beta$ -Ethoxydinitronaphthalene [$\text{NO}_2 : \text{NO}_2 : \text{EtO} = 1 : 2 : 4$] is formed, together with an isomeride (see below), when $\alpha\alpha$ -nitroethoxynaphthalene is gradually added to six times its weight of nitric acid (sp. gr. 1.43), cooled to -10° ; after the mixture has remained at 0° for 2—3 hours, the precipitated crystals are collected, treated with ammonia, boiled with light petroleum, and filtered from the undissolved portion. The compound separates from the filtrate in bright-yellow needles, which melt at 92—93°, or at 88° when finely powdered (compare Martius, *Zeit. Chem.*, 1868, 82); it is soluble in most organic solvents, and sparingly volatile with steam. It is readily converted into the corresponding dinitronaphthol (Martius' yellow) on boiling it with alcoholic potash, and into the dinitronaphthylamine melting at 236° on heating it in a sealed tube with alcoholic ammonia.

$\alpha\alpha\alpha$ -Ethoxydinitronaphthalene [$\text{NO}_2 : \text{NO}_2 : \text{EtO} = 2 : 1 : 1$, or $2 : 4' : 1$] represents the portion of the nitration product insoluble in light petroleum; when crystallised from alcohol with the use of animal charcoal, it forms small, lustrous plates, melts at 188°, and is sparingly soluble in cold alcohol; it forms the smaller portion of the nitration product. α -Nitrophthalic acid is produced when the ethoxy-derivative is heated with nitric acid (sp. gr. 1.14) in a sealed tube at 200°, or when the corresponding dinitronaphthol, obtained by boiling

the ethoxy-derivative with alcoholic potash, is oxidised with an alkaline solution of potassium permanganate. Ethoxytrinitronaphthalene, crystallising from alcohol in small, yellow plates melting at 170—171°, and tetranitronaphthol melting at 215° are obtained from the alcoholic filtrate from the last-described dinitro-derivative.

When the above-described $\alpha\beta$ -ethoxynitronaphthalene is nitrated, a very small quantity of the dinitro-derivative of melting point 92—93° is formed, but the chief product is a compound melting at 132°. A. R. L.

Hydrogenation of the Naphthoic Acids. By W. v. SOWINSKI (*Ber.*, 24, 2354—2363).—Preliminary experiments showed that when the naphthoic acids are heated at 200° with hydriodic acid and phosphorus, the products no longer possess acid properties.

Dihydro- α -naphthoic acid is formed when 3 per cent. sodium amalgam (300 grams) is added to a solution of α -naphthoic acid (10 grams) in the requisite quantity of aqueous sodium carbonate, diluted with water (300 grams), and cooled to 0°; the mixture is shaken, and the temperature kept below 5° during the reaction. The solution is nearly neutralised with dilute sulphuric acid, filtered, and an excess of dilute acid added to the cooled filtrate, when the acid separates after a time as a crystalline precipitate. It melts at 76°, and is almost insoluble in cold water, readily in hot; the *silver salt* is a white, voluminous precipitate, slightly soluble in hot water; the *copper salt* is a bright, bluish-green precipitate, very sparingly soluble in water; whilst the *calcium* and *barium salts* are easily soluble. The free acid separates on concentrating the aqueous solution of the *ammonium salt*, and when the latter is heated with a solution of mercuric chloride, the odour of naphthalene is developed. When the acid is distilled over heated soda-lime, naphthalene is produced. It yields a *dibromide* when dissolved in carbon bisulphide and treated with bromine; this is converted into a *monobromhydronaphthoic acid* by cold aqueous sodium carbonate; the last-mentioned acid decomposes, and yields naphthalene when boiled with aqueous sodium carbonate.

When the above described dihydro- α -naphthoic acid is boiled with a dilute solution of sodium hydroxide, or when α -naphthoic acid is treated with sodium amalgam at the ordinary temperature without cooling, a more stable isomeric *dihydro- α -naphthoic acid* is obtained; this melts at 112°, both the acid and the salts closely resembling their isomerides; it yields a crystalline *dibromide*, which melts at 136° with decomposition. Alkalis decompose it in the cold, but more quickly on heating. The two dihydro- α -naphthoic acids probably have the constitution $C_6H_4 < \begin{smallmatrix} CH(COOH) \\ CH=CH \end{smallmatrix} > CH_2$ and $C_6H_4 < \begin{smallmatrix} C(COOH) \\ CH_2-CH_2 \end{smallmatrix} > CH$ respectively.

Ac-tetrahydro- α -naphthoic acid is produced when a solution of α -naphthoic acid (7 grams) in amyl alcohol (80 grams) is allowed to drop in a thin stream on to metallic sodium (6 grams), and the mixture boiled. The sodium salt is then dissolved out by shaking with water, the small quantity of amyl alcohol dissolved in the aqueous

solution being removed by extracting it with ether; the excess of ether is driven off, and the liquid nearly neutralised, filtered, and an excess of acid added to the filtrate; the oil which separates is then extracted by agitation with ether, and the ethereal solution evaporated, when a hard mass having the odour of valeric acid is left. This is repeatedly dissolved in alkali, and reprecipitated with acid, whereby it is ultimately obtained in the form of small, white needles; it melts at 80° , and is very slightly soluble in cold water, much more so in hot, and very readily in other solvents. The *silver* and *barium salts* are easily soluble in water; the free acid is formed on evaporating a solution of the *ammonium salt*, and naphthalene is obtained on distilling it over soda-lime. The acid is not altered by boiling with water, or with aqueous sodium hydroxide; it forms substitution derivatives with bromine. The same tetrahydronaphthoic acid is obtained when dihydro- α -naphthoic acid (m. p. 112°) is heated with sodium amalgam.

Dihydro- β -naphthoic acid is formed in a similar manner to the α -derivative (m. p. 76°) from sodium amalgam and β -naphthoic acid. It melts at 103° , and is sparingly soluble in cold water, easily in hot water, and in other solvents. The *silver salt* is fairly soluble, and the *copper salt* sparingly so in hot water; whilst the *calcium* and *barium salts* are readily soluble in water. When the solution of the *ammonium salt* is boiled with mercuric chloride, the odour of naphthalene is perceptible. The acid forms a *dibromide*, which appears to be as unstable as the α -derivative of m. p. 76° . A more stable *isomeride* is obtained when the last-described modification is boiled for 5–6 hours with sodium hydroxide solution in a reflux apparatus, or by the action of sodium amalgam at the ordinary temperature on β -naphthoic acid; this melts at 158° , and crystallises from alcohol in small, iridescent plates; when treated with bromine, hydrogen bromide is evolved.

Tetrahydro- β -naphthoic acid is best prepared by boiling dihydronaphthoic acid (m. p. 158°) with sodium amalgam; it is also formed when β -naphthoic acid is dissolved in a large quantity of amyl alcohol, and boiled with sodium. It melts at 94° , forms substitution derivatives with bromine, and is not decomposed by boiling with water or alkalis. All the above hydrogenised acids are oxidised by permanganate in the cold, and the more stable dihydro-acids are less soluble than their isomerides, the tetrahydro-acids being still less soluble; the same applies to the salts.

A. R. L.

α - and β -Naphthylazoacetoacetic Acids and their Derivatives. By G. ODDO (*Gazzetta*, 21, 264–271).—*Ethyl α -naphthylazoacetoacetate*, $C_{10}H_7N_2CHAcCOOEt$, is prepared by mixing aqueous solutions of α -diazonaphthalene chloride and ethyl sodacetoacetate in molecular proportion; the yield is almost theoretical. When pure, it crystallises from dilute alcohol in bright-yellow, microscopic tables, melts at 93 – 94° without decomposition, dissolves very freely in alcohol, ether, and benzene, but is insoluble in water. The action of potash on this substance varies with the concentration and with the temperature, either α -naphthylazoacetone or the compound $C_{10}H_7N_2CH_2COOH$ being formed.

α-Naphthylazoacetone, $C_{10}H_7N_2 \cdot CH_2 \cdot Ac$, is prepared by dissolving the preceding compound in a 10 per cent. solution of potash at 100° ; on cooling, a dark red precipitate separates, which, after repeated treatment with dilute alcohol and animal charcoal, crystallises in microscopic, elongated, golden-yellow prisms, which melt without decomposition at $158-160^\circ$. It dissolves very freely in alcohol, but less so in ether, benzene, &c. It is not altered by boiling with potash.

α-Naphthylazoacetic Acid.—This acid is precipitated in bulky, yellow flakes on adding hydrochloric acid to the mother liquors obtained in the preparation of the preceding compound. The crude product melts at $135-140^\circ$, and probably has the composition $C_{10}H_7N_2 \cdot CH_2 \cdot COOH$.

Naphthylazoacetoacetic Acid.—The *α*-naphthyl acid, like acetoacetic acid, decomposes when attempts are made to isolate it; the *β*-naphthyl acid is, however, more stable. Its *potassium derivative*, $C_{10}H_7N_2O_2K + 3H_2O$, is obtained by the action of potash on the corresponding ethyl derivative, which is prepared in a similar manner to the *α*-naphthyl salt. It crystallises from alcohol in irregular, yellowish plates, and melts with decomposition at $206-208^\circ$. The free acid, $C_{10}H_7N_2 \cdot CHAc \cdot COOH$, is obtained by hydrolysing the potassium salt; it separates from alcohol in light flakes, consisting of yellow, microscopic, rectangular tables. It melts with decomposition at $198-200^\circ$, and dissolves in alcohol, ether, and benzene.

It is to be noted that the analogous azobenzene- and azotoluene-acetoacetic acids prepared by Meyer and Züblin (*Abstr.*, 1878, ii, 880) do not undergo the acid and ketonic decompositions of ethyl acetoacetate.

S. B. A. A.

Hydroxy-derivatives of Alizarin-blue. By R. E. SCHMIDT and L. GATTERMANN (*J. pr. Chem.* [2], 44, 103-109).—*Dihydroxyalizarin-blue*, $C_{17}H_7NO_4(OH)_2$, prepared from amidoquinizarin (this vol., p. 935), is almost insoluble in the ordinary solvents, and, like the other derivatives of alizarin-blue described in the paper, is best crystallised from nitrobenzene. It forms blue needles, which have a coppery lustre and closely resemble indigo in appearance, and its vapour is violet-blue in colour, like that of iodine. In concentrated sulphuric acid it dissolves with a greenish-blue colour, and the solution shows two marked absorption bands in the red and orange.

A trihydroxyalizarin-blue, $C_{17}H_5NO_4(OH)_3$, is obtained when alizarin-blue is warmed with 20 times its weight of 80 per cent. anhydrousulphuric acid at $30-40^\circ$ for several days. It crystallises from nitrobenzene, and on heating, sublimes in dark-blue needles. In sulphuric acid it dissolves with a greenish-blue colour, similar to that given by dihydroxyalizarin-blue, and the solution gives similar, but somewhat narrower, absorption bands.

The formation of a trihydroxyalizarin-blue by the action of fuming sulphuric acid on alizarin-blue led the authors to examine the colouring matters "alizarin-blue-green," "alizarin-green," and "alizarin-indigo-blue," obtained by the Badische Anilin- und Soda-Fabrik (German Patents, 46654, 47252) by the action of anhydrosulphuric acid on alizarin-blue, with the object of determining not only their

nature, but also their relationship to the substance produced from alizarin by the action of the same reagent.

"Alizarin-blue-green," prepared by treating alizarin-blue with 10 times its weight of 70 per cent. anhydrosulphuric acid and warming the product with twice the quantity of sulphuric acid of 66° Baumé for some time at 50—60°, can be readily purified by conversion into its compound with sodium hydrogen sulphite, dissolving this in water, precipitating with salt, repeating the process several times, and finally decomposing with hydrochloric acid. It crystallises well, and is a *hydroxyalizarin-blue-sulphonic acid*, $\text{OH}\cdot\text{C}_{17}\text{H}_7\text{NO}_4\cdot\text{SO}_3\text{H}$, which, on hydrolysis with concentrated hydrochloric acid at 160—170°, is converted into hydroxyalizarin-blue.

Hydroxyalizarin-blue, $\text{C}_{17}\text{H}_7\text{NO}_4\cdot\text{OH}$, may also be obtained on the large scale by heating "alizarin-blue-green" with 10 times its weight of sulphuric acid of 60° Baumé (78 per cent. H_2SO_4) at 140—145° for some hours. The product of the reaction is a crystalline *sulphate* of the composition $\text{C}_{17}\text{H}_7\text{NO}_4\cdot\text{OH} + \text{H}_2\text{SO}_4$, which, when heated with aqueous sodium acetate for a short time, yields the hydroxy-base.

"Alizarin-green," formed by heating "alizarin-blue-green" with 10 times its weight of pure sulphuric acid (100 per cent. H_2SO_4) for six hours at 120—130°, is readily purified by conversion into its compound with ammonium hydrogen sulphite, which, after dissolution in water, can be precipitated by potassium chloride, and when pure decomposed by hydrochloric acid. It crystallises in slender, greyish-violet, silky needles, and is a *hydroxyalizarin-blue-sulphonic acid*, $\text{OH}\cdot\text{C}_{17}\text{H}_7\text{NO}_4\cdot\text{SO}_3\text{H}$, isomeric with "alizarin-blue-green," being formed from this by hydrolysis and subsequent sulphonation in another position in the molecule. This is shown by the fact that both the greens, together with hydroxyalizarin-blue, can be isolated from the melt if the reaction is stopped when a test sample dissolved in strong sulphuric acid gives a solution showing the maximum shade of blue. Moreover, on hydrolysis with concentrated hydrochloric acid, "alizarin-green," like "alizarin-blue-green," yields hydroxyalizarin-blue.

"Alizarin-indigo-blue" contains as chief constituent a trihydroxyalizarin-blue isomeric with that just described. When "alizarin-blue-green" is heated with 20 times its weight of sulphuric acid of 66° Baumé at 200—210°, the solution, after a time, gives almost the same absorption bands as the solution of the quinoline derivative of "alizarin-claret" already described; but, on continuing the heating, these become fainter, and at the end of five hours can hardly be observed. The product thus formed is a *trihydroxyalizarin-blue*, $\text{C}_{17}\text{H}_5\text{NO}_4(\text{OH})_3$, which can be crystallised from nitrobenzene. The technical product obtained by heating "alizarin-green" with sulphuric acid at 200—210° contains, in addition to this substance, a sulphonic acid which does not dissolve in nitrobenzene, and on hydrolysis with concentrated hydrochloric acid, yields a *dihydroxyalizarin-blue*, $\text{C}_{17}\text{H}_7\text{NO}_4(\text{OH})_2$, whose absorption spectrum is identical with that of the quinoline derivative of "alizarin-claret." The examination of these colouring matters is being continued. W. P. W.

Essence of Myrtle. By P. BARTOLOTTI (*Gazzetta*, 21, 276—282).—The essence of myrtle (*Myrtus communis*), when purified by redistillation over calcium chloride, is a colourless, mobile liquid, soluble in alcohol, ether, &c., but only very sparingly in water; the aqueous solution has, however, the strong, characteristic odour of the essence. The sp. gr. of the essence is 0.881 at 27°, and it is dextrorotatory, $[\alpha]_D = +55.4$.

By continued distillation it may be split up into four fractions: *a*, about 19 per cent., passing over at 152—160°; *b*, about 29 per cent., at 160—162°; *c*, about 21 per cent., at 162—165°; and *d*, 26 per cent., at 165—180°. All of these are colourless, neutral liquids, the first only having the odour of myrtle, the others smelling of mint. A small quantity of water always passes over with the first portions of every distillate even if the essence is completely dried before distillation. This takes place even when the distillation is conducted in an atmosphere of carbonic anhydride, and led the author to suspect the presence of an oxidised compound in the essence. The greater part of the fraction *a* consists of a terpene, $C_{10}H_{16}$, which, after purification and repeated redistillation, passes over at 154—155°. It is a colourless, very mobile liquid with a somewhat unpleasant odour, and dissolves in alcohol and ether, but not in water. Its sp. gr. at 27° is 0.857, and its rotatory power $[\alpha]_D = +59.3$. The hydrocarbon distilling at 163°, separated by Gladstone (this Journal, 1864, 17, 1) from essence of myrtle, appears to contain an admixture of an oxidised compound. On heating it with sodium, a slow reaction takes place, and the residue consists of a terpene, $C_{10}H_{16}$, distilling at 160°. This is a colourless, very mobile liquid with an odour of turpentine. Its sp. gr. at 27° is 0.860, and the specific rotation $[\alpha]_D = +53.6$. The last portions of the distillate from the essence of myrtle yield on fractionation a substance having the composition $C_{10}H_{16}O$. It is a colourless, mobile liquid with an odour of peppermint, and turns yellow when exposed to the light for a time; it dissolves in alcohol and ether, but not in water. Its sp. gr. at 27° is 0.896, and its specific rotatory power $[\alpha]_D = +24.8$. S. B. A. A.

Terebic Acid. By G. CORSELLI (*Gazzetta*, 21, 271—276).—On heating terebic acid with alcoholic ammonia for six hours at 160—170° and distilling the product on the water-bath, the residue contains an acid compound of the composition $C_6H_{11}O_2N$, which crystallises from water in plates, melts at 204°, and dissolves very freely in alcohol, and moderately in ether. It also dissolves in the alkali hydroxides and carbonates, and in ammonia on heating, and in nitric and concentrated hydrochloric acid on prolonged boiling; from the latter solution, it separates unaltered on cooling. It forms a red solution with sulphuric acid. The silver salt, $AgC_6H_{11}O_2N$, forms small, white crystals readily affected by light. On treating the acid with nitrous acid, a nitroso-derivative is formed, which has the composition $C_6H_{11}N_2O_2$. It separates from alcohol in small, colourless crystals which melt at 170°, and give Liebermann's reaction for nitroso-compounds.

When a mixture of terebic acid and aniline in molecular propor-

tion is heated for half an hour at 155° , the product has the composition $C_{12}H_{18}NO$, and crystallises from water in white, prismatic needles, melts at 153 – 154° , and dissolves in water, alcohol, ether, and benzene. On heating it with a 30 per cent. solution of potash for a few hours, aniline and pyroterebic acid are formed.

The *acetyl derivative*, $C_{12}H_{14}ONAc$, crystallises from water in nodules, melts at 175° , and dissolves in alcohol and ether.

S. B. A. A.

Resin obtained from Thwaites' "Doona zeylanica." By E. VALENTA (*Monatsh.*, 12, 98–106).—This resin was exhibited in the Colonial Exhibition of 1887, held in London. It has a sp. gr. of 1.1362 at 17.5° , and melts on being strongly heated, at the same time turning brown and emitting a pleasant odour. It burns in the air with a brilliant flame, leaving 0.007 per cent. of ash, consisting of the carbonates of calcium and of the alkalis, with a small quantity of oxide of iron.

By successive treatment of the resin with different solvents, three distinct resins may be separated; one of these, the α -resin, has acid properties, whilst the other two, the β - and γ -resins, are neutral substances.

The α -resin is isolated by exhausting the finely-powdered Doona-resin with 4–5 times its weight of 90 per cent. alcohol, at 30 – 35° . On evaporating the solution thus obtained, it leaves a yellow, friable mass which resembles American colophony in appearance. This melts at 115° , gives, on elementary analysis, numbers corresponding with the formula $C_{24}H_{38}O_2$, is readily soluble in methyl, ethyl, and amyl alcohols and in hot fatty oils, and is readily nitrated by a mixture of nitric and sulphuric acids. The iodine number, determined by Hübl's method, is 60, and 1 gram of the resin requires 0.023 gram of potassium hydroxide to completely neutralise it. On distillation under a reduced pressure of 150 mm., a yellow, oily liquid, containing small quantities of acetic and formic acids, distils over at 110 – 140° ; whilst at a temperature of 180 – 200° , a solid, light-yellow, neutral resin is the product. The Doona-resin contains about 65 per cent. of the α -resin.

The β -resin is obtained when the residue left in the preparation of the α -resin is exhausted with ether. It forms a colourless, tasteless, and odourless mass, which softens at 120° and melts at 150 – 160° . It is soluble in ether, benzene, toluene, and xylene, and on elementary analysis gives numbers which correspond with the formula $C_{21}H_{33}O$.

The γ -resin is obtained by treating that portion of the Doona-resin which is insoluble in alcohol and ether with light petroleum; on evaporating, an almost colourless, transparent, brittle mass is obtained, which is insoluble in methyl, ethyl, and amyl alcohols, in ether, acetic acid, and amyl acetate, but dissolves readily in toluene and xylene; these solutions, on evaporation, give a shellac which is colourless and almost unaffected by acids and alkalis. The γ -resin is only slowly dissolved by sulphuric acid, and forms nitro-products with fuming nitric acid. On elementary analysis, it gives numbers corresponding with the formula $C_{31}H_{46}O$. The amount of β - and γ -

resins contained in Doona-resin is about 15 and 20 per cent. respectively. It is to be noted that a difference of $C_{10}H_{16}$, the formula for a terpene, exists in the above-given formulæ for the β - and γ -resins.

G. T. M.

Gentisin. By S. v. KOSTANECKI (*Monatsh.*, 12, 205—210; compare this vol., p. 1244).—*Gentisem*, obtained by boiling gentisin with hydriodic acid, melts at 315° . It is soluble in alkalis with a yellow colour, gives a blood-red coloration with sodium amalgam, and a deep-red precipitate with acids. In contradistinction to gentisin, gentisem dyes wool a pale-yellow in presence of an aluminium mordant; the hydroxyl group, which in gentisin is methylated, thus appears to have tinctorial properties.

Triacetylgentisem, $C_{13}H_4O_2(OAc)_3$, melts at 226° , and is more sparingly soluble than diacetylgentisin.

J. B. T.

Gentisin. By S. v. KOSTANECKI and E. SCHMIDT (*Monatsh.*, 12, 318—322).—*Dimethoxygentisem*, $C_{11}H_8O_5(OMe)_2$, can be obtained by heating gentisem or gentisin with potash and methyl iodide in methyl alcoholic solution at 100° ; it crystallises from glacial acetic acid in broad, yellow needles, melts at 167° , and is sparingly soluble in alcohol; its alkali derivatives are intensely yellow compounds.

The *acetyl* derivative, $C_{13}H_6O_5(OMe)_2OAc$, crystallises from alcohol in colourless needles, and melts at 189° .

F. S. K.

Quercetin and its Derivatives. By J. HERZIG (*Monatsh.*, 12, 172—176 and 177—190).—Quercetin is probably represented by the formula $C_{15}H_{10}O_7$, for this agrees better with the analytical results than Löwe's formula $C_{15}H_{12}O_7$. That the molecular weight is not represented by a multiple of 292 is shown by determinations of the boiling points of solutions of quercetin and acetylquercetin ethyl ether in ethyl alcohol. The old formula for quercetin is $C_{24}H_{16}O_{11}$, for fisetin $C_{23}H_{16}O_9$; there is thus a difference of CO_2 ; chemically, however, quercetin behaves like a hydroxy-fisetin; this difficulty disappears if the formula for quercetin given above is adopted. The following results prove that in all probability fisetin has the formula $C_{15}H_{10}O_6$, and that quercetin is a monhydroxy-derivative. The author is able to confirm Schmidt's observations on fisetin, but fisetin methyl ether can be obtained in long, colourless, glistening needles melting at 151 — 153° , by repeated recrystallisation from alcohol. The ethyl ether yields fisetin on treatment with hydriodic acid. Protocatechuic acid and resorcinol are formed when fisetin is dissolved in potash, and the solution allowed to remain exposed to the air for 24 hours, whilst quercetin, under similar conditions, yields protocatechuic acid and phloroglucinol.

On heating ethoxyfisetin, $C_{15}H_8O_5(OEt)_4$, on the water-bath with 10 parts of alcoholic potash for 7—8 hours, and saturating the solution with carbonic anhydride, a compound is deposited which is termed *fisetol ethyl ether*; it crystallises from dilute alcohol in colourless needles, melts at 42 — 44° , and gives a pale-red coloration with ferric chloride, which disappears on the addition of alkali carbonates. The mother liquors from the phenol contain diethoxyprotocatechuic acid.

Fisetol diethyl ether has the formula $C_8H_9O_2(OEt)_2$, and appears to be derived from *fisetol*, $C_8H_9O(OH)_2$, which has not yet been isolated; it is probably a resorcinol derivative, with one hydroxyl group in a side chain, and contains an aldehydic or ketonic group. *Fisetol triethyl ether*, $C_8H_9O(OEt)_3$, is prepared by the action of potash and ethyl iodide on the diethoxy-derivative; it crystallises from dilute alcohol in long needles melting at $66-68^\circ$, decomposes on further heating, and is not hydrolysed by alcoholic potash.

Fisetol dimethyl ether, $C_8H_9O_2(OMe)_2$, is prepared from *fisetin tetramethyl ether* in a similar manner to the ethyl derivative; it crystallises in small, colourless needles which melt at $66-68^\circ$. The *trimethoxy-derivative* is deposited from dilute alcohol in small, colourless needles melting at $62-63^\circ$, and is unacted on by potash.

Fisetol dimethyl ethyl ether, $C_8H_9O(OMe)_2OEt$, crystallises in lustrous needles melting at $60-62^\circ$. J. B. T.

The Bark of *Gonolobus condurango*. By G. CARRARA (*Gazzetta*, 21, 204-212).—The bark is extracted with strong alcohol, and the filtered solution allowed to cool; a greenish powder (A) falls, leaving a yellowish-brown solution (B). On treating A with ether, it is divided into a soluble part (a), and a yellowish, insoluble powder (b); the latter is purified by dissolving it in boiling alcohol, allowing the solution to cool, and washing the deposit repeatedly with alcohol and ether. It proves to be a glucoside of the composition $C_{40}H_{74}O_8$, which melts at 112° , and is insoluble in ether and light petroleum, sparingly soluble in cold alcohol, and very slightly in water; the aqueous solution is not precipitated by potassium mercuric iodide, or by a solution of iodine and potassium iodide. When boiled for some hours with dilute sulphuric acid, the liquid reduces Fehling's solution.

The glucoside, when heated with benzoic chloride at 100° , forms a benzoyl derivative, $C_{40}H_{72}O_8Bz$; this can be purified by precipitation from its solution in chloroform by alcohol. It is a brownish-red powder, insoluble in alcohol, water, and light petroleum, very soluble in chloroform, but only sparingly in ether; it blackens at 250° , and melts with decomposition above 270° . On evaporating the mixture of alcohol and chloroform from which this compound is deposited, a white powder is left, which melts at 72° , and yields benzoic acid when boiled with potash solution; a sufficient quantity for complete examination could not be obtained.

The substance a is boiled with alcoholic potash, the alcohol evaporated, the residue taken up with water, and extracted with ether; on evaporation, a yellow powder is obtained, showing the colour reactions of cholesterol, but melting at 52° and having the composition $C_{20}H_{36}O_2$; this compound the author names *conduransterin*.

The aqueous solution remaining after extraction of the *conduransterin* by ether contains cinnamic acid.

The original extract B has not yet been fully examined.

W. J. P.

Synthesis of Ethylpyrroline. By C. U. ZANETTI (*Gazzetta*, 21, 248-250).—The author has previously shown (Abstr., 1890, 202) that the product of the action of ethyl iodide on potassium pyrroline contained

1-ethylpyrroline, together with a quantity of another ethylpyrroline, which it was not found possible to identify with certainty. By the action of acetic anhydride, two products are obtained, in which the acetyl is united to carbon and nitrogen respectively; the former boils between 245° and 255° , and the latter between 200° and 240° . The first of these was converted into the *cinnamyl* derivative,

by heating with benzaldehyde and potash. The product, when pure, crystallises in yellow, lustrous needles melting at 150° , and soluble in boiling alcohol and ether, but not in water. On treating its alcoholic solution with a similar solution of silver nitrate, and adding a few drops of alcoholic ammonia, the silver derivative separates as a bulky, yellow precipitate. This ethylpyrroline is consequently identical with that prepared by Dennstedt and Zimmernann (Abstr., 1886, 1043), by the action of paraldehyde on pyrroline in presence of zinc chloride.

S. B. A. A.

Pyridinebetaines. By M. KRÜGER (*J. pr. Chem.* [2], 44, 130—136; compare this vol., p. 941).—Hofmann (Abstr., 1881, 921) has also noticed the production of a blue colour when alkylpyridylammonium halides are reduced with sodium amalgam in aqueous solution (compare this vol., p. 941). The author has further investigated the conditions under which this coloration is produced, and summarises the results of his experiments as follows:—All pyridine compounds formed by the addition of pyridine to halogen-substitution derivatives of the alkyl series give a blue colour when reduced with sodium amalgam, zinc-dust, or iron-dust in aqueous or alcoholic solution; the products of the reduction are double bases, formed by the combination of two pyridine rings through the opening out of a double bond in each ring (compare Abstr., 1881, 921). This colour reaction furnishes a convenient method for deciding whether a substance under investigation is a *pyridonium* compound or not.

The alkylidides of the homologues of pyridine give double bases of the same nature when they are reduced with sodium amalgam, but no coloration has been noticed by the author, and Hofmann does not mention whether a change of colour occurs or not.

Pyridinechlorhydrin, $\text{C}_5\text{NH}_2\text{Cl}\cdot\text{C}_2\text{H}_5(\text{OH})_2$, is formed when monochlorhydrin is heated for 6—8 hours with pyridine at 125 — 130° ; it crystallises from alcohol in small, feebly lustrous, six-sided, apparently rhombohedral crystals, melts at 105 — 107° , and dissolves in water and alcohol, but not in ether. Its aqueous solution gives an intense-blue colour with sodium amalgam, if warm, and a purple-violet in the cold. The free base, obtained by treating the chlorhydrin with moist silver oxide, is strongly alkaline, and precipitates the oxides of the heavy metals; it can, however, only be obtained in dilute solution, for it decomposes when concentrated. The *platinochloride*, $\text{C}_5\text{H}_{10}\text{O}_2\text{N}\cdot\text{H}_2\text{PtCl}_6$, forms lustrous, orange-red scales, and melts at 180° (uncorr.) with decomposition; the *aurochloride* forms lemon-yellow, feebly-lustrous scales, and melts at 122° .

Both pyridinechlorhydrin and pyridinecholine are converted into

pyridinebetaine when oxidised with chromic acid in sulphuric acid solution.

A. G. B.

Oxidation of Quinoline Derivatives. By G. v. GEORGIEVICS (*Monatsh.*, 12, 304—317).—The behaviour of a number of quinoline derivatives on oxidation has been investigated, with the following results:—

When para- and ana-quinolinebenzocarboxylic acid are oxidised with potassium permanganate under various conditions, some of the acid is completely destroyed, but quinolinic acid is not produced in either case; paratoluquinoline yields paraquinolinebenzocarboxylic acid as the principal product, but no quinolinic acid is formed.

When orthoquinolinebenzocarboxylic acid is oxidised with potassium permanganate in concentrated sulphuric acid solution, quinolinic acid is obtained; when, however, quinoline is treated with the oxidising agent in dilute sulphuric acid solution, it yields metaquinolinebenzocarboxylic acid (m. p. 246°), the formation of which is probably due to the production of a diquinolyl as an intermediate product.

On treating paraquinolinebenzocarboxylic acid with potassium permanganate in alkaline solution, it gives quinolinic acid and a carboxy-derivative of nitrobenzene; the latter compound is also formed in some of the other reactions referred to above, but it is obtained in such small quantities and is so difficult to purify that its composition could not be determined.

When paraquinolinesulphonic acid is oxidised with potassium permanganate in alkaline solution, it yields oxalic acid, very small quantities of quinolinic acid, and the nitrobenzene derivative just mentioned.

These and other experiments proved that the formation of quinolinic acid by the oxidation of quinoline with potassium permanganate, and also of those derivatives which are obtained from it by substituting hydrogen in the benzene nucleus, is, in some cases, dependent on the conditions of the experiment, but that in others quinolinic acid is not formed under any circumstances; the position and the nature of the substituting group also have a considerable influence on the course of the reaction.

F. S. K.

Ichthulin. By G. WALTER (*Zeit. physiol. Chem.*, 15, 477—494).—Ichthulin, the chief proteid constituent of the yolk of fishes' eggs, was prepared in large quantities by Valenciennes and Frémy (*Compt. rend.*, 38, 471) from salmon roes, and subjected to elementary analysis. The results of analysis in the present research gave the following percentage results:—

	C.	H.	N.	O.	S.	P.	Fe.
I	53·52	7·71	15·64	22·19	0·41	0·48	0·10
II	53·33	7·56	15·63	23·48			

The general properties of the substance show that it belongs to the

class of vitellins. On peptic digestion, it yields, as vitellin does, a nucleïn, which differs from the nucleïn of nuclei in yielding no nitrogenous bases like guanine, adenine, &c., on further decomposition. Simultaneously with the appearance of this para-nucleïn, a reducing carbohydrate is formed. W. D. H.

The Proteïds or Albuminoids of the Oat Kernel. By T. B. OSBORNE (*Amer. Chem. J.*, 13, 385—413).—In this, the concluding portion of his memoir (this vol., p. 1285), the author fully describes the extraction of the various proteïds from oats, and reviews the whole subject in a summary, of which the following is an abstract:—

1. The proteïd removed from freshly-ground oats by direct extraction with weak alcohol—called gluten by Norton—when dehydrated by absolute alcohol and dried over sulphuric acid, is a light-yellowish powder, insoluble in water and absolute alcohol, but soluble in mixtures of alcohol and water and in dilute acids and alkalis, from which it is thrown down on neutralisation. It separates from its solution in 60 per cent. alcohol, by evaporation, as a yellowish, slimy mass. It is remarkable for its content of sulphur (see below), in which it is only exceeded by keratin among the proteïds.

2. When the above substance is heated with dilute alcohol for some time, it coagulates and becomes insoluble in that liquid, but without apparent change of composition. The oat-gliadin of Kreusler and Rütthausen was a product of the further alteration of this substance by the treatment it received to purify it.

3. If oats are first treated with water or 10 per cent. solution of common salt, before extraction with dilute alcohol, the proteïd soluble in alcohol undergoes alteration; the resulting substance is much more soluble in dilute alcohol than that mentioned in 1, and is not transformed into an insoluble modification. When wet with absolute alcohol, the moisture attracted from the air makes it gummy, unlike 1. In composition it is nearly the same as the gliadin, or plant-gelatin, obtained by Dumas and Cahours and by v. Bibra.

4. Weyl states that the chief proteïd extracted by cold 10 per cent. solution of salt behaves towards reagents like the myosin-globulin from animal muscle; this is so, but it coagulates at 80—100°, which is higher than the temperature at which animal myosin coagulates (55—60°). This proteïd appears to be the result of a transformation similar to that by which myosin is formed from myosinogen, and is very similar to myosin in composition; 1.3 per cent. was the most obtained.

5. The proteïd extracted, after complete exhaustion of the oats with alcohol of 0.9 sp. gr., by 10 per cent. salt solution and that dissolved by dilute potash have so nearly the same composition as the globulin extracted by salt solution directly, that they may be regarded as originally identical, 4 (see below) representing the soluble, and 5 and 5a the insoluble, or “albuminate,” form.

6. When ground oats are directly extracted by dilute potash, without previous treatment with water or dilute alcohol, nearly the whole of the proteïds is dissolved. The substance so extracted, after completely removing the substance soluble in dilute alcohol, is perhaps the

same as the avenine of Johnston and Norton, who extracted oats with dilute ammonia.

7. One hour's treatment of oats with water rendered one-half, and 24 hours' treatment two-thirds, of the proteïds insoluble in 0.2 per cent. potash solution. The portion soluble in potash after action of water (and removal of the proteïd soluble in alcohol) has the same composition as the globulin soluble in salt solution (see below). It is probably the same substance as Krensler's oat-legumin, and Norton's "protein substance," extracted by dilute ammonia.

8. When ground oats are extracted with 10 per cent. solution of salt at 65°, a proteïd separates, on cooling, in the form of spheroids; it differs in composition and properties from all proteïds hitherto described; it dissolves in pure water, is precipitated therefrom by a little salt, redissolved by a further addition, and completely precipitated by saturation with salt. In presence of a little salt and acetic acid, it dissolves in alcohol of 0.9 sp. gr. It has been obtained crystallised in regular octahedra, from solutions in distilled water, as well as from those in salt solution.

9. The aqueous extract of ground oats was found, in agreement with Norton and Krensler, to contain very little proteïd matter; what is dissolved appears to be, first, an acid-albumin; second, a globulin or globulins similar in reactions to that extracted by 10 per cent. salt solution; and third, a proteose. No true albumin was found in the water extract.

10. In the salt extract, a very small amount of a substance having the reactions of albumin was found, but not analysed.

The following table gives the composition of the proteïds from the oat kernel referred to in this paper; the number at the head of each column denotes the proteïd described in the correspondingly numbered paragraph above:—

	1.	2.	3.	4.	5.	5a.	6.	7.	8.
Carbon	53.06	53.10	53.70	52.84	52.48	52.45	53.49	52.49	52.22
Hydrogen	6.94	6.91	7.00	7.21	6.94	6.92	7.01	7.10	6.98
Nitrogen	16.38	16.49	15.71	16.88	16.85	16.63	16.39	17.11	17.85
Sulphur	2.26	23.50	1.76	0.88	0.57	0.81	0.99	0.80	0.77
Oxygen	21.38		21.83	22.69	23.16	23.19	22.12	22.50	22.18
	100.00	100.00	100.00	100.00	100.00	100.00	100.00	100.00	100.00

A. G. B.

The Viscous Material formed by the Bacterium *gliscrogenum*. By P. MALERBA (*Zeit. physiol. Chem.*, 15, 539—545).—Large quantities of the slimy substance, gliscrin, formed by the growth of the *B. gliscrogenum* were obtained by growing it in urine. Alcohol was then added, the precipitated material dissolved in water, reprecipitated by alcohol, and well washed with alcohol and water acidified with acetic acid. After long standing under concentrated alcohol, it becomes insoluble in water. It is nitrogenous, and gives the various

proteid reactions. Albertoni at one time considered that it was a carbohydrate, and it is possible that in the impure state there may be carbohydrate mixed with it, but no direct proofs of this were found in the present research.

W. D. H.

Physiological Chemistry.

Formation of Lactic Acid and Glucose in the Organism. By T. ARAKI (*Zeit. physiol. Chem.*, 15, 546—561; compare this vol., p. 1125).—In the research of which this is the continuation, the diminution of oxygen in the body was shown to be a cause of the appearance of sugar and lactic acid in the urine. Morphine and other narcotics have often been observed to produce glycosuria. It is now shown that they also cause the appearance of lactic acid in the urine; thus the cause of the glycosuria is probably here also a diminution of oxygen in the organism. The animals used were frogs, rabbits, and dogs. The drugs employed were morphine, amyl nitrite, and cocaine, and of these amyl nitrite is especially powerful in producing excretion of lactic acid.

W. D. H.

Carbohydrates in the Urine. By E. ROOS (*Zeit. physiol. Chem.*, 15, 513—538).—The normal urine of the dog, rabbit, and horse contains a certain quantity of carbohydrates, most in the dog, least in the rabbit.

The results obtained by the furfuraldehyde reaction were confirmed by the benzoic chloride method.

With human urine, the phenylhydrazine reaction always gives a positive result. The same is true for dog's urine. Rabbit's urine gives especially well-formed crystals. In the case of the urine of the dog and horse, preliminary precipitation by lead acetate is necessary. The urine of all these animals is slightly laevorotatory.

W. D. H.

Influence of Wool on the Material Exchange of Sheep. By E. KERN, H. WATTENBERG, and T. PFEIFFER (*Bied. Centr.*, 1891, 451—454).—The amount of carbonic anhydride and nitrogen excreted by sheep when clothed with wool, immediately after shearing, and some considerable time after shearing, was determined. It was found that the production of carbonic anhydride increased considerably immediately after shearing; but when the sheep became accustomed to the new state of affairs, then the excretion fell to the normal amount. There was a slight reduction in the nitrogen excreted after shearing, and the amount of perspiration was considerably less.

E. W. P.

Production of Leucocytosis in Mammals. By J. HOBBACK-NEWSKI (*Monatsh.*, 12, 221—275).—See p. 1340.

Action of Definitely-related Chemical Compounds on Animals. By W. GIBBS and E. J. REICHERT (*Amer. Chem. J.*, 13, 361—370).—In this continuation of the authors' thesis (this vol., p. 1280), the action of the substances named hereunder on the respiration and circulation of frogs and dogs when administered subcutaneously, intravenously, and internally, is described.

Sodium Nitroprusside.—The fatal dose by the stomach is about 0.2 gram per kilo. of body-weight; by the vein, from 0.1—0.2 gram per kilo. The respirations are increased, the temperature falls, paralysis and general collapse supervene, and death ensues from failure of the heart's action.

Nitroso- β -naphthol.—When given to the dog by the stomach the blood is discoloured, becoming very dark, and exhibiting by means of the spectroscope the presence of nitrite of hæmoglobin. The fatal dose, subcutaneously, is about 0.4 gram per kilo., and is, relatively, very large, owing to slowness of absorption; the heart's action becomes sluggish, the motor reflexes are weakened and, finally, abolished, the heart being arrested in diastole. Intravenously, about 0.04 gram per kilo. is fatal. Internal administration causes persistent vomiting, which prevents determination of the fatal dose. Death is due to paralysis of the respiratory centres.

Nitromethane.—The minimum lethal dose is from one-half to 1 c.c. per kilo. of body-weight. Lassitude, drowsiness, and vomiting occur; sleep passes into stupor, and then into coma, respiration fails, and the heart ceases to beat.

Nitrosodiethylene.—The minimum fatal subcutaneous dose is less than 1 c.c. per kilo.; intravenous, from one-third to one-half c.c. per kilo. Its action is somewhat similar to that of nitromethane.

Hydroxylamine.—The blood becomes much discoloured, almost black, owing to formation of methæmoglobin; general paralysis occurs, and death supervenes from a failure of respiration. The lethal internal dose for the dog is about 0.2—0.3 gram per kilo.; intravenously it is 0.06 gram per kilo.

Aldehyde-ammonia.—The lethal dose subcutaneously injected is 0.15—0.2 gram per kilo.; intravenously injected, it is about 0.04 gram per kilo. Blood pressure, pulse, and respiration rapidly fail, and death results primarily from paralysis of the respiratory centres.

Furfuraldehyde Sodium Hydrogen Sulphite.—The lethal dose, intravenously, is 0.3—0.5 gram per kilo.; 3 grams per kilo. injected subcutaneously killed a dog within 24 hours. There is a decrease of pulse, respiration, and temperature; repeated doses cause further reductions, and death ensues from cardiac paralysis.

Oxamic acid and cyanuric acid may be considered inert.

Alcohols.—The action of all the alcohols which the authors have examined is identical with that of ethyl alcohol, but different in degree. Dogiel (*Pfluger's Arch.*, 8, 605) found that methyl alcohol was the least toxic of the first five alcohols, and amyl alcohol the most. Dujardin-Beaunmetz and Andigé (*Compt. rend.*, 83, 80—82) found that methyl alcohol was less poisonous than ethyl alcohol, and that, in passing from ethyl to amyl alcohols, toxicity regularly increased. The minimum lethal doses of the

alcohols which were examined by the authors were, when intravenously injected, as follows in c.c. per kilo. of body-weight:—Propyl, 1.6—2.5; isopropyl, 1.3—2; butyl, 0.3—0.6; isobutyl, 0.6—0.7; secondary butyl, 1.0—1.5; tertiary butyl, 1.0—1.2; heptyl, 0.1—0.12; octyl, 1.05—0.1 (*sic*); allyl, 0.2—0.24; benzyl, 0.4—0.6; cuminyl, 0.25—0.3. A. G. B.

Chemistry of Vegetable Physiology and Agriculture.

Secretions of Microbes; Transformation and Elimination of Organic Matter by the Pyocyanic bacillus. By A. ARNAUD and A. CHARRIN (*Compt. rend.*, 112, 1157—1160).—When the pyocyanic bacillus acts on asparagine (this vol., p. 1132) 72.5 per cent. of the carbon is eliminated in the form of carbonic anhydride; 13.8 per cent. forms part of the protoplasm of the microbes and the remainder exists in the form of soluble compounds. The quantity of oxygen absorbed is in proportion to the quantity of carbonic anhydride evolved. In a vacuum, evolution of carbonic anhydride takes place slowly; in an atmosphere of carbonic anhydride there is no development of the microbe; in hydrogen there is considerable development, with formation of ammonia.

With gelatin and the necessary salts, the evolution of nitrogen is more regular than with asparagine, but the quantity of ammonia does not increase after the 22nd day. The quantity of nitrogen converted into ammonia is 70 per cent., whilst with asparagine it is 91 per cent. On the other hand, the weight of the microbes and of the products of secretion is considerably greater with gelatin than with asparagine. No pigment is formed, but the products of secretion have marked toxic action. The volatile portions and the portions soluble in alcohol are toxic in large doses and protective in small doses; the portion insoluble in alcohol is toxic, and has no vaccinating effect in small doses. C. H. B.

Substitution of Manganese for Iron in Plant Nutrition. By G. SPANPANI (*Staz. Sper. Agrar.*, 19, 5—33).—Water culture experiments were made with oats, white lupins, and maize. There were three series of experiments: in the first (A), the plants were grown in a solution of potassium phosphate (5 grams), calcium nitrate (8 grams), magnesium sulphate (1 gram), and potassium chloride (0.5 gram), 14.5 grams of the mixed salts being dissolved in 14.5 litres of water; in the second series (M), the same solution was employed, with the addition of 7 or 8 drops per litre of manganese sulphate solution (about 0.05 per cent.); in the third (F), ferric chloride was used in the place of manganese.

The appearance of the plants at various periods of growth is described. It was found that the ashes of the leaves of plants grown with manganese gave an intense manganese reaction. But in

all cases it was found that manganese could not take the place of iron in the formation of chlorophyll. N. H. M.

Physiology of the Tannins and Trihydroxybenzenes. By E. NICKEL (*Chem. Centr.*, 1891, i, 1041; from *Bot. Centrbl.*, 1891, 1—4).—The author has already expressed the opinion that the tannins are derived from the trihydroxybenzenes, some being derivatives of the symmetrical phloroglucinol, others being derived from pyrogallol and hydroxyquinol, and the tannins may be, therefore, divided into those which have a "symmetrical" origin, and those of an unsymmetrical origin. The tannins do not show any difference in their chemical reactions, however.

The author further expresses the opinion that phloroglucinol is derived from inosite, which, according to Maquenne, is readily converted into tri-iodobenzene and aromatic compounds.

J. W. L.

Experiments with Green Maize. By Z. v. SZILASSY and A. CSERHÁTI (*Bied. Centr.*, 1891, 463—469).—Of all fodder plants which have a low percentage of proteids, but a heavy total yield, maize takes the first place; all others are either below it in quality or in total yield. When thickly sown, maize requires much water, and, therefore, a wet soil is necessary; but the thicker the sowing is, the smaller are the individual plants; although, at the same time, the total yield is better than when the plants stand further apart.

The earlier ripening kinds, as Cinquantino and Székler, are of better quality than the later ripening sort. E. W. P.

Formation of Nitrates in Soils. By A. MÜNTZ (*Compt. rend.*, 112, 1142—1144).—Nitrites are only found in soils in very small quantities and under exceptional circumstances, whilst on the other hand when the nitrifying organisms are introduced into cultivation fluids, large quantities of nitrates are formed.

Dilute solutions of calcium nitrite undergo no change when left in contact with oxygen for many months. Calcium nitrite is, however, decomposed by carbonic acid with liberation of nitrous acid, a relatively large quantity of carbonic acid being necessary in order to secure complete decomposition. Simultaneous action of oxygen or air and carbonic anhydride on solutions of calcium nitrite completely convert it into nitrate, oxidation taking place when nitrifying organisms are entirely absent.

If calcium nitrite is added to a soil which has previously been heated for half an hour at 100° in order to kill the nitrifying organisms without killing those which produce carbonic anhydride, the nitrite after a few days is completely converted into nitrate.

It seems highly probable, therefore, that the nitrifying organism converts the nitrogen into nitrites, and the latter are converted, without any further action of any organism, into nitrates by the simultaneous action of the oxygen and carbonic anhydride which are always present in soils. C. H. B.

Depreciation of Manure by Exposure to Wet and Fermentation. By ROBERTS and WING (*Bied. Centr.*, 1891, 437—438).—

Horse stable manure was exposed to the weather in a box in a manure heap; there was, after the lapse of half a year, a loss in total weight, an increase in water, and a decrease in the percentage of valuable matter. When horse and cow manure were treated under like conditions, but the drainage collected, there was found to be a loss of the nitrogen to the extent of 3.2 per cent., of the phosphoric acid 4.7 per cent., and of the potash 35 per cent. But *thin* layers of manure exposed to the sun and air and rain lost scarcely anything. E. W. P.

Analytical Chemistry.

Strength of Solutions estimated by their Refraction. By H. O. G. ELLINGER (*J. pr. Chem.* [2], 44, 152—157).—See p. 1305.

Electrolytic Separations. By E. F. SMITH and F. MUHR (*Amer. Chem. J.*, 13, 417—422).—The most favourable result, together with the conditions under which it was attained, is here quoted from the list of experiments given in each case.

Gold from Palladium.—Gold present, 0.1162 gram; potassium cyanide, 1.50 grams; total volume, 150 c.c.; current in c.c. OH gas per minute, 0.8; palladium present, 0.12; gold found, (1) 0.1162, (2) 0.1163, (3) 0.1162, (4) 0.1163 gram.

Gold from Copper.—Gold present, 0.1725 gram; potassium cyanide, 1.50 grams; total volume, 150 c.c.; OH gas per minute, 0.8 c.c.; copper present, 0.125 gram; gold found, 0.1725.

Gold from Cobalt.—Gold present, 0.1792 gram; Potassium cyanide, 3 grams; total volume, 150 c.c.; OH gas per minute, 0.6 c.c.; cobalt present, 0.15—0.2 gram; gold found, 0.1789.

Gold from Nickel.—Gold present, 0.1725 gram; potassium cyanide, 2.5 grams; total volume, 150 c.c.; OH gas per minute, 0.5 c.c.; nickel present, 0.1373 gram; gold found, 0.1724 gram.

Gold from Zinc.—Gold present, 0.1792 gram; potassium cyanide, 3 grams; total volume, 150 c.c.; OH gas per minute, 0.6 c.c.; zinc present, 0.2 gram; gold found, 0.1790 gram.

Gold from Platinum.—Gold present, 0.1467 gram; potassium cyanide, 2.5 grams; total volume, 150 c.c.; OH gas per minute, 1 c.c.; platinum present, 0.2433 gram; gold found, 0.1468 gram.

Silver from Platinum.—Silver present, 0.077 gram; potassium cyanide, 2.5 grams; total volume, 150 c.c.; OH gas per minute, 1 c.c.; platinum present, 0.2433 gram; silver found, 0.0772 gram.

Cadmium from Platinum.—The precipitated cadmium always contained platinum. (Compare Abstr., 1890, 1029.)

Mercury from Platinum.—Mercury present, 0.1902 gram; potassium cyanide, 2.5 grams; total volume, 150 c.c.; OH gas per minute, 0.2 c.c.; platinum present, 0.2433 gram; mercury found, 0.1900 gram.

Details of difficulties met with in some of these separations will be found in the original paper. A. G. B.

Estimation of Nitrogen in Nitrates by Kjeldahl's Method. By L. F. KEBLER (*Chem. News*, 63, 302—303).—Having investigated various points, the following conclusions are arrived at:—1. Kjeldahl's method is not as accurate as the absolute method for estimating nitrogen in nitrates, but is executed much more rapidly, and is applicable for all practical purposes. 2. To avoid loss of nitric acid, the sulphuric acid must be added quickly. 3. The end of the condenser should dip into the liquid in the receiver. 4. The addition of a metallic oxide economises time. 5. The potassium permanganate must be added to complete oxidation. 6. It is unnecessary to add zinc to the contents of the distillation flask, in order to prevent bumping.

D. A. L.

Estimation of Total Phosphoric Acid in Manure. By F. MARTINOTTI (*Staz. Sper. Agrar.*, 19, 614—616).—The ammonium molybdate method when employed in estimating the total phosphoric acid in manures is liable to error when a certain amount of iron is present, owing the formation of a ferric phosphate insoluble in nitric acid. This is precipitated when the hydrochloric acid used for the extraction of the phosphates is driven off by nitric acid. Analyses of basic slag and mineral phosphates are liable to this error. The following method is recommended:—5 grams of the manure suspended in water (15 c.c.) is treated with hydrochloric acid (30 c.c.) and boiled for half an hour. The whole is evaporated to dryness on a water-bath and again treated with acid (20 c.c.) and evaporated to dryness. The residue is moistened with hydrochloric acid (5 c.c.), treated with boiling water (15 c.c.), heated on a water-bath for 10 minutes, filtered, and washed with boiling water. The filtrate is diluted to 100 c.c.; of this 50 c.c. is treated with aqueous ammonium citrate (125 c.c.; 1 c.c. = 0.4 gram of citric acid), neutralised with ammonia, and diluted to 250 c.c.; a portion of this solution (100 c.c.) is then treated with distilled water (50 c.c.), ammonia (50 c.c.), and magnesia mixture (50 c.c.), well stirred, and left for 12 hours, after which it is filtered and the ammonium magnesium phosphate determined as usual. The method gives very concordant results.

N. H. M.

Note.—The formation of tetrahydrated ferric phosphate was already shown by Arth to be a probable source of error in the estimation of phosphates in slags (*Abstr.*, 1890, 292).

N. H. M.

Estimation of Silica in presence of Iron. By LEBLER (*Compt. rend.*, 112, 1132—1133).—The decomposition of ferric chloride in the estimation of silicon can be prevented by adding potassium chloride, which forms the double ferric potassium chloride. 1 gram of metal is dissolved in 20 c.c. of nitric acid and 10 c.c. of hydrochloric acid and boiled with two successive quantities of 30 c.c. of hydrochloric acid in order to expel the greater part of the nitric acid. It is then mixed with 3 grams of ammonium chloride and evaporated to dryness to expel the last traces of nitric acid. The residue is dissolved in hydrochloric acid, mixed with 3 grams of potassium chloride and

some water, and again evaporated to dryness. The residue is treated with strong hydrochloric acid and afterwards with water.

If ammonium chloride is not present, the silica may contain manganese, and if all the nitric acid has not been expelled, it may contain potassium. Chromium redissolves completely if the residue is treated with strong hydrochloric acid, but solution is rendered certain by reducing a small quantity to chromous chloride by adding zinc or aluminium.

C. H. B.

Alkalimetry of the Blood. By H. WINTERNITZ (*Zeit. physiol. Chem.*, 15, 505—512).—The alkalinity of the blood was determined by titration with decinormal tartaric acid instead of a mixture of sodium sulphate and tartaric acid, as recommended by v. Jaksch (*Zeit. Klin. Med.*, 13); the blood is received from the vessel of a living animal through a graduated pipette provided with a stopcock. Provided small quantities are employed, this is available for clinical use. The reaction is determined by litmus paper. The mean alkalinity of 100 c.c. of normal rabbit's blood is 0.165 gram. It is well known that the alkalinity of the blood decreases on coagulation; this diminution is stated to take place in two stages, namely, before and during coagulation. If, however, the alkalinity of fresh blood be immediately neutralised, no further change in reaction occurs. Further, the diminution of alkalinity takes place even though coagulation is hindered by addition of salt solution, but the diminution is not so great as when coagulation occurs. A further question, whether the quantity of oxygen present influenced the result, is answered in the negative.

W. D. H.

Estimation of Sodium Chloride in Wine. By J. GONDOIN (*J. Pharm.* [5], 24, 8—10).—Test paper is prepared by painting filter paper in streaks with a 10 per cent. solution of potassium chromate; this paper should only be prepared in small quantity at a time and should be kept in well-stoppered blue or yellow bottles. A standard solution of silver nitrate is employed (7.25 grams per litre) such that 4 c.c. precipitates 0.01 gram of chlorine, corresponding with 1 gram of sodium chloride per litre, the assay being made on 10 c.c. of wine. The silver solution is run into the wine until a drop of the mixed liquid placed on the test paper gives a brick-red precipitate in addition to the reddish-grey due to the wine alone.

J. T.

Decomposition of Chromite by the Electric Current. By E. F. SMITH (*Amer. Chem. J.*, 13, 414—417; compare Abstr., 1889, 926).—30—40 grams of stick potash is melted in a nickel crucible and gently heated until the excess of moisture has been expelled. The crucible is held in a heavy copper wire ring attached to the anode of a storage cell, and is heated by a small flame throughout the decomposition. From 0.1 to 0.5 gram of the finely-divided chromite is brushed from a watch glass upon the liquid alkali, the crucible covered with a perforated glass, and a platinum rod, attached to the cathode, lowered into the melted mass. The current, which should not exceed 1 ampère, is then set in action and continued for 30 to 40 minutes; particles projected from the surface of the melt by the

bursting gas bubbles will be returned to the crucible by the drops which collect on, and fall from, the glass cover. Before finally interrupting the current, it should be reversed for a short time by means of a commutator; this is because metallic iron is deposited on the cathode and may enclose particles of the ore, which will thus remain unattacked.

After the current has been interrupted, the crucible is digested in water until the melt is dissolved, and after some further digestion the liquid is filtered and the residue washed; this residue should dissolve completely in hydrochloric acid unless quartz be present in the ore. The estimation of the chromium in the aqueous solution and washings is best performed by the addition of a known weight of ferrous sulphate to the acidified liquid and determining by standard dichromate the portion of this salt which remains unoxidised.

A. G. B.

Estimation of Sugar in Blood. By M. ARÉLES (*Zeit. physiol. Chem.*, 15, 495—504).—The usual method of getting rid of the proteids in the blood before estimating the sugar is either to boil with sodium sulphate and acetic acid (Bernard) or with sodium acetate and ferric chloride (Schmidt-Mulheim, Seegen). Schenk (this vol., p. 350) has stated that the former method leads to a considerable loss of sugar, although several other observers have found that the loss is not so great as Schenk states, and explain it in a different way. There are also objections to Schmidt-Mulheim's method which the present author has previously pointed out (*Wien. Med. Jahrb.*, 1887). He now recommends a new, simple, and efficacious method, and illustrates its accuracy by a table of analyses. The procedure is the following:—To the blood is added an equal volume of a solution of zinc acetate in absolute alcohol. The strength of this solution should be such that for each gram of blood 0.05 gram of zinc acetate is added. The precipitate is filtered off, squeezed, and washed with alcohol, the washings being added to the filtrate; to the latter a 20 per cent. solution of sodium carbonate is added until the reaction is strongly alkaline, and the precipitated zinc carbonate is filtered off. The filtrate is acidified with acetic acid and evaporated to 20—30 c.c. (50 c.c. of blood is usually taken). A few drops of a concentrated aqueous solution of zinc acetate is added, and then sodium carbonate until the mixture is alkaline; finally it is made up to the original volume and filtered, the sugar being estimated in this filtrate. Instead of zinc acetate, zinc chloride may be used.

W. D. H.

Estimation of Tannin and of Free Tartaric Acid in Wines. By A. VIGNA (*Staz. Sper. Agrar.*, 19, 279—298).—The following modification of Löwenthal's method for the estimation of tannin is recommended:—50 c.c. of the tannin solution or the wine mixed with 5 c.c. of ammoniacal zinc acetate solution (zinc acetate, 40 grams; ammonia in excess, and the whole made up to 1 litre) is heated in a dish on a water-bath, being stirred from time to time, until the volume is reduced to about one-third; water (50 to 60 c.c.) is added, the whole mixed and allowed to get cool, when it is filtered, and the pre-

precipitate washed with cold water. The precipitate is at once dissolved in dilute sulphuric acid (1 : 4; 10 c.c.) and boiling water in the dish already used. When cold, 20 c.c. of indigo solution (1 gram to a litre) is added, the liquid diluted to about 250 c.c., and permanganate added until the colour of the indigo disappears. By using cold solutions of about 250 c.c., and by carefully adding the permanganate drop by drop, good results are obtained. A point of importance is that the amount of permanganate required is not always proportional to the tannin. Experiments made with tannin solutions containing respectively 1, 2, 3, and 4 parts per million showed that the amount of permanganate required is relatively greater the stronger the solution; thus, the amounts required by 50 c.c. of the above solutions were respectively 9.7, 20.5, 32.0, and 44.0 c.c. The difference is, however, not great enough to be of practical importance. The experiments show that the separation of tannin in wines by zinc acetate is sufficiently complete if too great an excess of zinc salt is avoided and the precipitate is rapidly washed and redissolved. Ganter's method is discussed, and is not recommended.

With regard to the estimation of free tartaric acid in wines, the methods of Berthelot and Fleurien and of Barth, and the potassium chloride method, were tried. The direct determination with potassium acetate or chloride is the quickest, and gives results nearest the truth, especially when much acid is present. The addition of alcohol and ether may be omitted. The potassium chloride method is the simplest, and gives good results. N. H. M.

Detection of Sesame Oil in Olive Oil. By J. F. TOCHER (*Pharm. J. Trans.*, 21, 638—649).—A solution of pyrogallol in hydrochloric acid (2 grams in 30 c.c.) gives a reaction characteristic of sesame oil, after a sample of olive or other oil containing even a small proportion (1 per cent.) has been agitated with it. The hydrochloric acid solution, after having been separated from the oil, is boiled for five minutes, when the colour will be changed to purple, and the solution, after a time, will deposit a purple substance. The author also found that by agitation with acetic acid sesame oil yielded 0.04 per cent. of an extract which, by approximate treatment of the acid solution, was finally obtained in the form of fine, acicular crystals, melting at 117°, and soluble in alcohol and other solvents. It gave no reaction with the hydrochloric solution of pyrogallol, but by nitro-sulphuric acid was turned first green, and then bright red, an effect which has been already observed with sesame oil itself, and used as a test. The percentage composition of the substance was found to be : C, 30.53; H, 5.43; O (by difference), 64.04. R. R.

Analysis of a Mixture of Wax, Paraffin, Stearin, and Stearic Acid. By F. JEAN (*Bull. Soc. Chim.* [3], 5, 3—5).—3 or 4 grams of the mixture are treated with 60 c.c. of boiling alcohol. On cooling, the alcoholic solution is titrated with seminormal alkali, phenolphthalein being used as an indicator, and the stearic acid is thus determined, since 7.8 c.c. of seminormal alkali = 1 gram of stearic acid. To the above neutralised alcoholic solution, 3—4 c.c. of sodium

hydroxide solution (50 per cent.) is added, and the mixture is boiled in a reflux apparatus for one hour; the alcohol is now distilled off, and the residue is mixed with dry silica and asbestos, dried at 100° , and exhausted with hot chloroform; subsequent distillation of the chloroform leaves a residue of paraffin and myricic acid, which is weighed, and the paraffin is determined in a portion of this residue by heating it in a reflux apparatus with 4–5 c.c. of glacial acetic acid for one hour. The solution is now placed in a graduated tube, to which the rinsings of the flask with warm glacial acetic acid are added, and the tube and contents are placed in a water-bath at 90° , and frequently agitated. The volume of separated paraffin is read off and determined, since 1 gram of paraffin occupies under these conditions 1.35–1.4 c.c., and the myricic acid is taken by difference. The portion of the alcoholic residue which is insoluble in chloroform consists of sodium stearate, stearin, and cerotic acid. This is dissolved in boiling water, filtered from the silica and asbestos, and the solution decomposed by the addition of slight excess of nitric acid, the fatty acids are filtered off, and the filtrate is neutralised, treated with plumbic acetate, and the glycerol contained therein estimated by potassium dichromate; from the glycerol, the stearin is estimated on the assumption that 5 grams of glycerol are = 95 grams stearin, and the cerotic acid is taken by difference. T. G. N.

Estimation of Fats in Vaseline. By VIZERN and C. NICOLAS (*J. Pharm.* [5], 24, 49–51) —Caustic alkalis are without action on the normal constituents of vaselin in the process to be described, whilst they combine in definite proportions with the fats to form soaps. Experiment has determined that 10 grams of these fatty compounds absorb 1.635 grams of potassium oxide, K_2O , and the calculations are based on this. A standard alkali solution is prepared by dissolving about 20 grams of potash in 100 c.c. of 90° alcohol. This is standardised by means of standard sulphuric acid. A neutral alcohol is prepared by dissolving 1 c.c. of phenolphthalein in 500 c.c. of 90° alcohol, then alkali is stirred in drop by drop until a very slight rose tint is produced. 10 grams of the vaselin to be tested is placed in a 200-c.c. porcelain basin, 10 c.c. of standard alkali added, the basin being kept on a water-bath during the whole process. 50 c.c. of neutral alcohol is now added, the solution heated nearly to boiling, and the mixture stirred for eight minutes, when the saponification will be complete, and normal sulphuric acid added drop by drop until *all colour has disappeared*; this point is very important. If too long a time has been taken, it may be necessary to add a fresh portion of neutral alcohol to replace the loss by evaporation. The amount of sulphuric acid run in subtracted from that required to saturate 10 c.c. of alkali solution, multiplied by 0.0047, gives the quantity of potash absorbed by the fats in 10 grams of vaselin, and this number divided by 0.01635 gives the percentage of fats in the vaselin. J. T.

Optical Analysis of Butter Fat. By H. O. G. ELLINGER (*J. pr. Chem.* [2], 44, 157–159).—The author describes the testing of
VOL. LX. 5 a

butter fat in the "difference refractometer" (this vol., p. 1305). He records the deflection given by 510 samples of pure Danish butter, taken with the view of ascertaining to what extent the refraction of pure butter fat varies, and therefore to what extent the refraction of butter can be used as a test for its purity. The readings were made at a temperature of 45°, and the "normal oil" of Amagat and Jean was used in the middle cell.

The samples were taken between February and June (209), during September and October (174), and in November (57) and December (70). The mean deflections for these four periods were 30.5, 27, 30.5, and 33 divisions respectively; the greatest deflection given by any sample was 37, and the least 23 divisions. Commercial margarin always contains some butter fat; the sample which contained least, in the author's experience, gave a deflection of eight divisions; when this sample was mixed with an equal quantity of butter of 35 deflection, the reading given by the mixture was 21.5, or 1.5 below the lowest natural butter (23).

The author concludes that natural butter gives a deflection varying between 35 and 23 divisions, and that the refractometer can only detect with certainty more than 45 per cent. of admixed margarin.

A. G. B.

Estimation of Fat in Milk. By M. KÜHN (*Chem. Centr.*, 1891, i, 1007; from *Milch. Zeit.*, 20, 369—370).—For the estimation of fat in curdled milk, the author recommends Dietrich's method and weighing tubes.

The author also describes a small wire cage for holding the Adams' coils, which consists of two rings about 1 inch in diameter, into which the coil is slipped and weighed. The milk is then pipetted on to the coil, and the latter again weighed.

J. W. L.

Estimation of the total Alkaloids in Quinine Bark. By W. HAUBENSAK (*Chem. Centr.*, 1891, i, 1006—1007; from *Schweiz. Wochenschr. Pharm.*, 29, 147—151).—The author recommends the following method for the estimation of the total alkaloids in quinine bark in preference to that described in the *Pharm. Germ.* III; it differs from the latter in that the alkaloids are extracted from the ether-alcohol ammonia solution by agitation with dilute sulphuric acid, by which means the alkaloids are obtained free from resinous matters and wax.

20 grams of the finely-pulverised bark is shaken in a 500-c.c. flask with 10 c.c. of 10 per cent. ammonia and 20 c.c. of 94 per cent. alcohol; 170 c.c. of ether is added, and the whole shaken occasionally during 2—3 hours. 100 c.c. of the clear extract is poured off into a separating funnel, and shaken with 50 c.c. of water and so much sulphuric acid that the resulting liquid has a slightly acid reaction. The aqueous layer is allowed to separate from the ether, run off, warmed in order to expel the dissolved ether, and returned to the separating funnel; 30 c.c. of chloroform is then added, the alkaloids liberated by the addition of a few drops of caustic soda solution, and, after shaking well, the chloroform

extract is separated, run into a tared flask, and the chloroform distilled off. The residue is dried at 100° , and weighed. The alkaline liquid, after separating the chloroform, is tested with iodine solution or Meyer's reagent, and should give no alkaloid reaction; otherwise it must be again extracted with chloroform. The alkaloid residue is obtained crystalline, more or less yellowish coloured, clear and completely soluble in acidified water. The process occupies 4–5 hours, and the results obtained are satisfactory. J. W. L.

Estimation of Caffeine. By B. H. PAUL (*Pharm. J. Trans.*, 21, 882).—More caffeine is obtained from a mixture of tea with magnesia when extracted with chloroform than from a mixture of tea with lime; but in each case this menstruum fails to dissolve out, even after prolonged treatment, more than a fraction (one-half, one-third) of the caffeine actually present. Chloroform cannot therefore be substituted for alcohol in estimating the amount of caffeine in tea, and its employment may account for the smallness of the amounts of caffeine in tea that some analysts have reported. R. R.

Estimation of Morphine. By A. LAMBERT (*J. Pharm.* [5], 23, 593–597).—It is known that the rotatory power of morphine in acid solution diminishes as the solution becomes more concentrated. If p represents in grams the quantity of morphine (supposed hydrated) contained in 100 c.c. of solution, α° the deviation produced in a column 0.2 m. long, then $p = 31 - \sqrt{961 - 25\alpha}$. It is found by calculation and verified by experiment that, to produce a deviation of 10° saccharimetric (or 2.167° of arc), it is necessary to dissolve 1 gram of morphine in 112 to 113 c.c. To estimate the morphine in opium, 15 grams is treated with 6 grams of slaked lime and 150 c.c. of water added in small portions; after stirring occasionally, the liquid is filtered off at the end of half an hour. To 53 c.c. of the filtrate is added 1 c.c. of acetic acid, 2 c.c. of water, 1 gram of powdered sodium sulphite, and some fragments of zinc. After a quarter of an hour the solution is filtered and examined in the polarimeter: let N be the deviation in degrees. 60 c.c. of the first solution is now actively shaken with 3.5 grams of ammonium chloride during 10 minutes, filtered, and 41 c.c. of the filtrate is treated with 1 c.c. of acetic acid, 0.75 gram of sodium sulphite, and some small fragments of zinc. After a quarter of an hour, it is filtered and examined in the polariscope; let n be the deviation, then $N - n$ indicates the quantity of morphine contained in 100 parts of opium. J. T.

Optical Estimation of Albumin in Urine. By H. O. G. ELLINGER (*J. pr. Chem.* [2], 44, 256).—The author has employed Amagat and Jean's differential refractometer for the estimation of albumin in urine. A portion of the urine is boiled, after the addition of a drop of acetic acid, and the albumin removed; the filtrate is then made up to the original volume and introduced into the space bounded by the two parallel glass plates between the collimator and the telescope, whilst the original urine is put into the prism. If the zero of the instrument has been previously adjusted,

the boundary line between light and dark falls the further to the right of the zero the more albumin the urine contains. The method gives results which are exact enough for practical purposes.

A. R. L.

Estimation of Casein in Milk. By J. Roux (*Chem. Centr.*, 1891, i, 1094—1095; from *Moniteur Scientif.* [4], 5, 478—482).—The author recommends the following method, which is a modification of that of Adams, for the estimation of casein in milk; 10 c.c. of milk is extracted with 25 c.c. of the Adams' mixture of ether, alcohol, and ammonia, the aqueous layer is run off, the ether layer containing the fat is again washed with water, and the washings added to the aqueous layer, the volume of the whole now measuring 40—50 c.c. 2 c.c. of 50 per cent. trichloroacetic acid is added, the liquid shaken, and the precipitated casein collected on a tared double filter. It is then washed with 50 c.c. of water containing 1 c.c. of trichloroacetic acid, and the casein dried at 110°. If the milk should be curdled, it is well to shake it first with 1 or 2 c.c. of 25 per cent. ammonia, before extracting with the ether-alcohol mixture.

The filtrate from the casein does not react either with Esbach's or with Tanret's reagent, showing the absence of peptones, from which the author concludes that these compounds are either absent altogether, or present in fresh milk only in very small amount, since they are not precipitated by trichloroacetic acid, and must, therefore, be in the filtrate from the casein. It is to be noted that the presence of trichloroacetic acid can completely prevent the reduction of Fehling's solution by lactose.

J. W. L.

Estimation of Indigotin for Commercial Purposes. By F. A. OWEN (*Chem. News*, 63, 301—302; from *J. Amer. Chem. Soc.*, Jan., 1891).—The method, as previously described (*Abstr.*, 1890, 96), has been considerably modified. Two lots, of 1 gram each, of coarsely powdered indigo shavings are taken: in one, the moisture and ash are determined; the other is first pulverised dry, then levigated with water, the suspended portion poured off, and the process repeated, until all is transferred to a 200-c.c. flask; 3 grams of zinc-dust and 60 c.c. of commercial strong ammonia are then added, the flask filled to $\frac{1}{8}$ c.c. above the mark, and shaken occasionally until reduction is complete (possibly from half an hour to two hours); 50 c.c. of the clear solution is then put in an evaporating basin, 5 or 6 drops of ether added, and air blown through to precipitate most of the indigotin; a moderate excess of hydrochloric acid is now added, the whole heated to boiling, and the precipitated indigotin collected on a tared filter, dried at 100°, and weighed.

D. A. L.

General and Physical Chemistry.

Copper Oxide Battery. By F. DE LALANDE (*Compt. rend.*, 112, 1253—1256).—The element consists of one or more plates of zinc and a plate of agglomerated cupric oxide suspended in a 35 per cent. aqueous solution of potassium hydroxide. The zinc is supported by strips of amalgamated brass, and is completely immersed in the solution. The plates of copper oxide are prepared by subjecting a mixture of moist granular copper with 5 per cent. of clay to hydraulic pressure, and roasting the cakes at 600—700°, or by mixing the copper with 6 to 8 per cent. of tar and roasting in a reverberatory furnace. In order to give the requisite conductivity to the porous copper oxide, it is coated electrolytically with a very thin film of copper. The characteristics of this element are its low internal resistance, its great constancy, and its great yield of energy. The E.M.F. on open circuit is 0.94 volt.

C. H. B.

Electromotive Forces of Polarisation. By M. LE BLANC (*Zeit. physikal. Chem.*, 8, 299—330).—Starting with the assumption that electrolytes are present in a dissociated condition in aqueous solution, the author argues that the electrical energy required to separate the ions from the solution will be given by the product of the amounts of electricity peculiar to each ion into the intensities with which these amounts may be attached to the ions. The intensity of attachment will vary with the nature of the ion, but will always be the same for the same ion, provided that the influence which the solvent may be supposed to exercise on the dissolved substance remains constant. If the E.M.F. which is just sufficient to produce a separation of the ions from a solution of a given salt be accepted as a measure of the intensity of attachment of the electricity to the ions, constant differences might be looked for in the values of E.M.F. for salts having common ions.

The author has measured the above E.M.F. for normal solutions of a number of salts. The following table for salts of potassium and sodium shows that the constant differences predicted by the theory are actually obtained:—

	Diff.		Diff.
$\text{Na}_2\text{CO}_3 = 1.71$ volts		$\text{K}_2\text{CO}_3 = 1.74$ volts	
$\text{NaNO}_3 = 2.15$ "	0.44	$\text{KNO}_3 = 2.17$ "	0.43
$\text{Na}_2\text{SO}_4 = 2.21$ "	0.06	$\text{K}_2\text{SO}_4 = 2.20$ "	0.03
$\text{NaCl} = 1.98$ "	0.23	$\text{KCl} = 1.96$ "	0.24
$\text{NaBr} = 1.58$ "	0.40	$\text{KBr} = 1.61$ "	0.35
$\text{NaI} = 1.12$ "	0.46	$\text{KI} = 1.14$ "	0.47

Experiments with other salts serve to confirm the above results.

A number of sodium salts of organic acids were next examined, and it was found that all these gave about the same value, a value practically the same as that for the potassium salts.

tically equal to that for the nitrate and sulphate. As it is improbable that the intensity of attachment is the same for the organic as for the inorganic acids, this number must be regarded as the maximum value which the E.M.F. can reach. The existence of such a maximum value can, however, only be explained by assuming that in these cases we are dealing, not with different processes, but always with one and the same process. This process the author believes to be the primary electrolysis of the water by the current. The maximum value is therefore the value for the decomposition of water. If this is the case, it will be necessary to assume that the water is in a partially dissociated condition, and the electrolysis of any given salt, such as potassium nitrate, would then take place as follows:—The conduction of the current would take place solely by the ions of the salt, but in the neighbourhood of the electrodes the potassium (positive) would form potassium hydroxide with the hydroxyl group (negative) of the water, the remaining hydrogen then giving up its charge at the electrode; the NO_3 ion (negative) would combine with the hydrogen (positive) of the water, and the remaining hydroxyl group would give up its charge at the electrode. The above hypothesis serves to explain a number of facts which have hitherto remained unexplained, as for instance the production of pure oxygen at the positive electrode in the electrolysis of acetic and benzoic acids in dilute solution. H. C.

Specific Heats of some Solutions. By W. TIMOFÉEFF (*Compt. rend.*, 112, 1261–1263).—The author has determined the specific heats of solutions of mercuric chloride and cadmium iodide respectively in various proportions of methyl or ethyl alcohol. In all the solutions, the two salts have practically the same molecular capacity for heat, the mean value being 52. The specific heat in the case of methyl alcohol solutions is given with considerable accuracy by the formula $C = 0.56755 + 0.001633t$, and in the case of ethyl alcohol by the formula $C = 0.53574 + 0.002132t$.

The specific heat of cadmium iodide in concentrated aqueous solution is considerably lower than in alcoholic solution, whilst in dilute aqueous solutions it approaches that of the salt in the solid state.

C. H. B.

Heats of Neutralisation. By S. ARRHENIUS (*Zeit. physikal. Chem.*, 8, 419–424).—E. Wiedemann has sought to explain, without the aid of electrolytic dissociation, the equality of the heats of neutralisation of strong acids by strong bases in dilute solution, on the assumption that, for example, $(\text{K}, \text{Cl}) - (\text{K}, \text{Br}) = (\text{H}, \text{Cl}) - (\text{H}, \text{Br})$, the salts being supposed to be solid, and the acids gaseous.

Arrhenius shows from thermochemical data, that this assumption is not justified for the undissociated substances, solids or gases. Of 179 combinations tabulated, only 12 fulfil the condition.

Arrhenius also corrects a misstatement of Wiedemann's regarding the heat of dissociation of water and its temperature coefficient.

J. W.

Calculation of the Boiling Point of a Liquid under any Pressure. By G. HINRICHS (*Zeit. physikal. Chem.*, 8, 340–342).—

Against the logarithm of the pressure (p) in atmospheres as abscissa, the author tabulates the corresponding boiling point of a liquid as ordinate. A tangent to the curve thus obtained is drawn from the critical point (θ, π), and prolonged to cut the axis of abscissæ at the absolute zero in ξ_1 ($T = 0, \log p = \xi_1$). If $\delta = \log p - \xi_1$, then $Y_1 = K_1\delta$ (*Zeit. phys. Chem.*, 8, 231). By subtracting Y_1 from observed values of T , Y_2 is obtained, and is equal to $K_2\Delta^2$, where $\Delta = \log \pi - \log p$. K_1 and K_2 are numbers which may be deduced from the curves, and once they are known, the boiling point in the absolute scale of temperature for any pressure may be calculated from the formula $T = K_1\delta + K_2\Delta^2$. The author gives some examples of the excellent agreement between observed and calculated values (for carbonic oxide, ammonia, and chlorine), but in the case of water doubts the accuracy of the critical constants determined by Dewar, as here the agreement is not satisfactory.

J. W.

Vapour Density of Ammonium Chloride. By O. NEUBERG (*Ber.*, 24, 2543—2544).—The author has determined the vapour density of ammonium chloride under reduced pressure in the apparatus recently described by himself and Lunge (this vol., p. 635). Under a pressure of 25 mm., the vapour density was found to be 1.13 and 1.2; under 46 mm. pressure in an atmosphere of hydrogen chloride, it rose to 1.5, and under 60 mm. pressure in ammonia, to 1.68 and 1.71. The vapour density of unaltered ammonium chloride would be 1.85, and in case of complete dissociation 0.925. These results show, therefore, conclusively that the molecule of ammonium chloride can exist in the gaseous condition.

Similar experiments with sulphur gave values which point to the existence of the molecule S_8 .

H. G. O.

Vapour Pressure of Water up to 200 Atmospheres. By C. ANTOINE (*Compt. rend.*, 113, 328—331).—Cailletet and Colardeau give the following expression for the vapour pressure of water at any temperature t up to 325° , in atmospheres:—

$$t = \frac{1638 - 0.0005P^2}{5.0402 - \log P} - 225.$$

If the value of t is below 200° , the quantity $0.0005P^2$ is practically so small that it may be neglected. The author calculates and tabulates the values for $0.0005P^2$ above 200° , and also gives the values of P for every 10° from 220° to 360° .

H. C.

A Theorem of Willard Gibbs. By P. DUHEM (*Zeit. physikal. Chem.*, 8, 337—339).—Konovaloff has shown (*Ann. Phys. Chem.* [2], 14, 34 and 219) that when a mixture of two volatile liquids has a greater (or smaller) vapour pressure than any other mixture of the same components, then the composition of the liquid is the same as that of the vapour. Gibbs has deduced this result on theoretical grounds, and the author now gives a detailed proof of the following general theorem: In a system of two coexisting phases, in order that the pressure should be a maximum (or a minimum) at constant tem-

perature, or that the temperature should be a maximum (or a minimum) at constant pressure, it is necessary and sufficient that the two phases possess the same composition. J. W.

Calculation of Molecular Volumes. By G. HINRICHS (*Compt. rend.*, 113, 36—38).—The author in this paper communicates two methods of arriving at the molecular volume of the members of homologous series. He first supposes that the normal paraffins have molecules composed of n similar joints (CH_2 groups), and terminated at each end by a hydrogen atom. The volume of $\text{C}_n\text{H}_{2n+2}$ is thus $r_n = n \cdot k + 2h$. The volume h is diminished by the mutual attraction of the molecules, and this diminution reaches a maximum when $n = v$ (here 15), h being then equal to h' . For $n < v$ we may thus write $h = h' + k'(v - n)^2$, and $v_n = nk + 2(h' + \epsilon)$, where $\epsilon = k'(v - n)^2$.

Taking the constants $k = 17.8$, $h' = 3.45$, $k' = 0.1$, and $v = 15$, the accordance between theory and experiment is exceedingly good. The odd members of the series have in general values slightly below those calculated: the even members have values slightly in excess.

Another method is adopted in the case of the ethereal salts of the normal fatty acids, $\text{C}_q\text{H}_{2q-4}\text{O}_2\text{C}_p\text{H}_{2p+1}$. The molecule is here supposed to rotate on a longitudinal axis, and the oxygen atoms to determine the cross section of the solid of revolution. The author arrives at the formula $v_n = n \times 24.6 + 2\epsilon$, where $p + q = n$, and $\epsilon = 1.25(7 - n)$. J. W.

Capillarity Constants of Organic Substances in Aqueous Solution. By J. TRAUBE (*Annalen*, 265, 27—55).—In investigating the subject of capillarity, the author and others have hitherto only paid attention to the capillarity constants a^2 and a ($= \gamma$), constants whose values are given by the capillarity equations $a^2 \cos \theta = rh$ and $a \cos \theta = r h s / 2$. It seemed desirable, therefore, to study the capillarity of molecular solutions and, by subtracting the constants of the solution from those of water, to obtain others which would show the influence of the nature, number, and size of the dissolved molecules. Such constants would be a measure of the capillary forces exerted by the molecules in solution, and, assuming that no dissociation or association phenomena accompany a change in concentration, it follows that the constants $a_w^2 - a_1^2 = \epsilon^2$ and $a_w - a_1 = \epsilon$ (compare Abstr., 1885, 1033; 1887, 101) must increase proportionately with the concentration c , or, in other words, the products of concentration and capillarity, ϵ^2 and ϵc , must be constant. This being the case, it would follow that a law, corresponding with Boyle's law for gases, is also true for dilute solutions. As the concentration increases and the molecules coalesce to more complex aggregates, the values of ϵ^2 and ϵc must decrease; from the magnitude of this decrease, and by determining the concentration at which the above expressions become constant, conclusions not without an important bearing on the dissociation or association phenomena of solutions might probably be drawn. The constants ϵ^2 and ϵc , which correspond exactly with the values μ for the molecular conductivity, may be termed the specific and the actual molecular cohesion respectively.

The detailed results of the examination of solutions of a number of monocarboxylic acids, alcohols, and ethereal salts of the fatty series, and also of various other fatty substances (some of which are mentioned below) are given in tables.

From a study of these results, it is seen that the molecular cohesion c_e increases as the concentration decreases, until a constant end value is approximated; this approximation to a constant value takes place at different concentrations with different substances. It has been previously shown by Buliginski, Quincke, and Volckmann that the quotient of the values c_e for solutions of most salts is approximately equal to unity for the concentrations $c = 1$ to $c = \infty$; roughly speaking, this is also true as regards solutions of the compounds of the oxalic series, of acetamide, and of ethylene glycol, so that Boyle's law holds good to a certain extent even for high concentrations. In the case of the fatty, monohydric alcohols, monocarboxylic acids, and ethereal salts formed therefrom, a considerable degree of dilution must be attained, especially when the compound is rich in carbon, before the ratio of the values c_e approximates to unity; nevertheless, the values obtained experimentally with the monocarboxylic acids, allyl alcohol, butaldehyde, and hydroxyisobutyric acid indicate clearly that with sufficiently dilute solutions, Boyle's law would hold good.

On comparing the author's results with those obtained by Ostwald in his studies on electrical conductivity, it is seen that the influence of concentration is, on the whole, very much the same in both cases, and there can be little doubt that the decrease of conductivity and the decrease of molecular cohesion with increasing concentration are both due to the same cause. The analogy between electrical conductivity and capillarity is also shown by the fact that the higher the capillary activity of a substance is, the lower, in general, is the electrical conductivity of its solution. Salts are capillary inactive but electrolytically active; most, or many, organic compounds show the opposite behaviour. Generally speaking, the greater the capillarity of a solution the greater also the conductivity, although many organic substances form exceptions to this rule; even in such cases the entrance into a molecule of the most various groups and atoms, as, for example, CH_3 , OH , H_2 , Cl , C_6H_5 , affects the two constants in a similar manner, and it is quite evident that the same assumption which is made to explain the change in electrical conductivity with a change in concentration must also be made in the case of capillarity.

The association hypothesis put forward by the author (*Ber.*, 23, 3582; compare this vol., p. 390) accounts for this change by assuming that as the concentration increases the molecules coalesce to form more complex aggregates; the following considerations will show that the capillarity constants afford a means by which these association phenomena may be determined numerically:—

(1.) In homologous series of capillary active substances, the (approximately) constant end values of the molecular cohesions for sufficiently dilute solutions are in the ratio $1 : 3 : 3^2 : 3^3 \dots$, or, in other words, the pressure which the dissolved molecules exert on unit of surface increases in homologous series of capillary active sub-

stances by the addition of CH_2 in the ratio $1 : 3 : 3^2 : 3^3 \dots$; this rule does not hold good in the case of members of the oxalic series, but only for capillary active substances.

If, by graphic interpolation, the concentrations corresponding with equal capillary pressure, that is to say, for isocapillary solutions, are calculated, conclusions of very considerable importance for the association theory can be arrived at, and, neglecting certain irregularities which are most evident at high concentrations, the following rules may be laid down. (2.) In homologous series of capillary active substances, the proportion between the number of molecules which exert equal pressure on the unit of surface is constant and almost independent of the number of the dissolved molecules. (3.) In isocapillary solutions of substances differing by $n\text{CH}_2$, the proportion between the number of molecules of the dissolved substances is as $1 : 3^n$.

Now if it be granted that, with increasing concentration, the molecules become associated to form larger aggregates, the fact that the law (1) stated above holds good even for high concentrations can hardly be accounted for except by the further assumption that, in such isocapillary solutions of homologous substances the association of molecules to aggregates is proportional to the number of simple molecules in solution; that is to say, the proportion between the more complex aggregates is the same as that between the simple molecules.

Assuming, again, the truth of the association hypothesis, it would seem, from the results obtained with solutions of high concentration that, with increasing concentration, the association of the molecules takes place proportionately to the number of the dissolved molecules.

In addition to the above statements, the following facts may be quoted as showing the relation between capillarity and constitution. The capillary constants of solutions of fatty acids are practically the same as those of the fatty ethereal salts with which they are metameric; propionic acid, for example, gives approximately the same values as methyl acetate, propyl formate the same as those of methyl propionate. Nevertheless, in the case of many isomerides, the arrangement of the atoms is not without influence, even in dilute solutions; although solutions of the two propyl alcohols, for example, and of the two butyric acids, have practically the same capillarity, this is not so in the case of isocamyl alcohol and its isomeride dimethylethyl carbinol.

In isocapillary solutions of propyl acetate and allyl acetate, the ratio between the number of dissolved molecules is $1 : 2$; this is also the case with solutions of the corresponding alcohols and amines, with dilute solutions of butaldehyde and isobutyl alcohol, propyl alcohol and acetone, succinic acid and maleic acid—compounds which differ from one another by 2 atoms of hydrogen. Ethylene glycol, although richer in hydrogen than acetic acid, has a considerably greater capillary constant.

The entrance of a hydroxyl group into a molecule always increases the capillarity, but by a different amount in different cases. The entrance of a carbon atom into the molecule of a capillary active

substance always diminishes the capillarity; the capillarity of butyric acid, for example, is to that of allyl acetate as 1 : 1.6 to 1.7, and the same is true as regards alcohol (or acetone) and allyl alcohol; in the case of propionic acid and butaldehyde, the ratio is 1 : 2, but the value of ϵ^2 for propionic acid is about 1/20 of that of ethylene glycol, and a similar irregularity is observed in the ratio of the values for maleic and malonic acids.

F. S. K.

Determination of Molecular Weight at the Critical Point. By P. A. GUYE (*Compt. rend.*, 112, 1257—1258).—If π , θ , and ϕ are respectively the pressure in atmospheres, the absolute temperature, and the volume of a weight p of a compound at the critical point, then the critical density with reference to air at 0° and 1 atmosphere is

$$d = \frac{p\theta}{F\phi\pi 273 \times 0.001293}.$$

d should be equal to the molecular weight divided by 28.87. F is a factor, having approximately the value 2.67, but this approximation is not sufficiently close. The author finds that it may be regarded as a linear function of the absolute critical temperature of the particular compound. Thus, $F = A(1 + B\theta)$. The numerical values of A and B as determined by means of the data for nitrogen (Sarrau) and iodobenzene (Young) are respectively 2.648 and 0.0009345. The first equation then becomes

$$d = 1146 \frac{\delta\theta}{\pi(1070 + \theta)},$$

δ being the critical density with respect to water or the weight of the substance occupying a volume of 1 c c. at the critical point.

The values obtained for hydrogen, ethylene, carbonic anhydride, sulphurous anhydride, ethyl alcohol, normal propyl alcohol, chlorobenzene, and iodobenzene by means of this equation are identical with the theoretical densities.

C. H. B.

Cryoscopic Observations. By A. VAN BIJLERT (*Zeit. physikal. Chem.*, 8, 343—366).—Van't Hoff (Abstr., 1890, 1044) accounted for the abnormally small depression of the freezing point exhibited by some solutions on the assumption of the solid which separates on congelation not being the pure solvent, but an isomorphous mixture containing a quantity of the dissolved substance. The author has put this explanation to an experimental proof, and has investigated the following solutions; thiophen in benzene, metacresol in phenol, antimony in tin, and β -naphthol in naphthalene. The quantity of solution adhering to the crystals was estimated from special experiments with the solution to be examined and a third substance which did not crystallise out with the solvent.

In the case of thiophen dissolved in benzene, the author found, in five experiments with solutions of different concentrations, that the ratio of the thiophen in the crystals to that in the mother liquor was 0.41, 0.44, 0.17, 0.14, 0.14. The last three numbers were obtained from the most successful experiments, so the author concludes that

on the partial congelation of thiophen-benzene solution, there is a crystallisation of thiophen to the extent of about 10 per cent. of that originally contained in the solution.

Although solutions of metacresol in phenol have an abnormally high freezing point, the author was unable to show by the method he adopted that any of the dissolved substance crystallised along with the solvent.

With antimony dissolved in tin, and β -naphthol in naphthalene, there is actually an elevation of the freezing point instead of a depression. This is accounted for by the solid which crystallises containing more dissolved substance than the solution itself. The following numbers were found :—

	Antimony, per cent.	β -naphthol, per cent.
Original solution	5.0	9.1
Mother liquor	4.7	8.5
Crystals	6.3	11.5

J. W.

Solution. By J. A. WANKLYN and W. J. COOPER (*Chem. News*, 64, 27—28).—The authors have made observations from which they conclude that solution is simple and regular except where influenced by chemical action. There is no change in volume or temperature when sugar is dissolved in water, the volume of the solution being equal to the sum of the volumes of sugar and water; for every gram of sugar entering into 100 c.c. of the solution, a regular rise of 0.00371 in the specific gravity is observed.

A contraction of 9 c.c. occurs when 73.7 grams of sodium chloride is dissolved in a quantity of water equal to 500 c.c. less the volume of the salt taken; the solution obtained has a specific gravity of 1.0988; the increment for each gram of salt per 100 c.c. of solution being 0.00670, this number increases to 0.00709 in a solution containing 1.474 grams of salt. Sodium bromide or iodide shows less contraction and less variation in the increased gravity than in the case of the chloride; the number for the bromide is 0.00741 for 50.2 and 0.00757 for 10.04 grams per 100 c.c. of solution, whilst for the iodide the numbers are 0.00737 for 41.01 and 0.00747 for 8.202 grams per 100 c.c. of solution. Anhydrous barium chloride dissolves with development of heat; an 18.372 gram solution shows an increase in specific gravity equal to 0.00795 for each gram of the salt, whilst each gram of anhydrous calcium chloride showed an increase of 0.00675. A solution containing 62.1 grams of $\text{MgSO}_4 \cdot 7\text{H}_2\text{O}$ in 100 c.c. had a sp. gr. of 1.271.

D. A. L.

Nature of Colloidal Solutions. By C. BARUS and E. A. SCHNEIDER (*Zeit. physikal. Chem.*, 8, 278—298).—A study of the properties of colloidal solutions leads to the conclusion that such solutions consist of very finely divided matter which is held in suspension in the solvent. In order to obtain evidence as to the correctness of the above view, the authors have examined the behaviour of colloidal silver solutions. Silver being an excellent conductor of electricity, a

measurement of the resistance of such solutions should aid in determining whether the silver particles are held mechanically in suspension in the solution, or are present as molecules in the dissolved state. In the first case the liquid would be a non-conductor, in the second metallic conductivity might be expected. The experiments show that colloidal silver, either in the solution or in the solid condition, is a non-conductor. These results, taken in conjunction with the other properties of colloidal solutions, confirm therefore the views expressed above as to the nature of such solutions. H. C.

Action between Oxides and Hydroxides of Heavy Metals and the Halogen Compounds of the Alkalis. By W. BERSCH (*Zeit. physikal. Chem.*, 8, 383—395).—A solution of potassium chloride reacts with mercuric oxide until a state of equilibrium is reached between these two substances and the mercuric chloride and potassium hydroxide formed. Such reactions have been investigated by the author with regard to the amount of alkali liberated at different temperatures. On the one hand, he used the oxides of mercury, cadmium, and lead; on the other, the chlorides, bromides, iodides, and thiocyanates of the alkalis and alkaline earths.

He sums up his results as follows :—

1. Some oxides (hydroxides) of heavy metals are capable of decomposing halogen compounds of the alkalis with formation of free alkali.

2. If the metal forms an insoluble compound with the halogen, then, if excess of oxide be present, all the halogen is abstracted from the solution.

3. If the compound of the halogen with the heavy metal is soluble, a state of equilibrium is finally reached.

4. This is dependent on the degree of dissociation of the dissolved substance. The more it is dissociated, the less is the amount of free alkali.

5. The state of equilibrium is influenced by the heat of reaction. If heat is absorbed, the quantity of free alkali increases with rise of temperature and *vice versa*.

6. The time required to reach the final equilibrium is dependent on the halogen; it is smallest with the iodides, and diminishes as the temperature is raised.

7. The amount of decomposition is dependent only on the halogen. The alkali metal with which the halogen is combined has very little influence in the reaction. J. W.

Velocity Coefficients of Bases. By S. BUGARSZKY (*Zeit. physikal. Chem.*, 8, 398—418).—The author measured the rate at which various alkalis saponified methyl acetate, and calculated from his data the coefficient of velocity in each case in absolute (C.G.S.) units. The following table contains his results :—

Velocity Coefficients.

	Dilution in litres.			
	20.	40.	80.	100.
KOH	132.9	129.2	—	—
LiOH	129.8	—	—	—
NaOH	127.2	126.4	124.1	—
Ba(OH) ₂	124.6	125.7	126.9	—
Sr(OH) ₂	—	121.6	—	—
Ca(OH) ₂	—	121.2	126.1	126.4

A comparison of conductivities (Ostwald, *J. pr. Chem.* [2], 33, 352) with velocity coefficients gives:—

Base.	Electrical conductivity. KOH = 1.	Velocity coefficient. KOH = 1.
KOH	1.000	1.000
NaOH	0.930	0.965
LiOH	0.888	0.972
Ba(OH) ₂	0.948	0.944
Sr(OH) ₂	0.911	0.915
Ca(OH) ₂	0.897	0.911

The temperature of experiment was 19.4°.

J. W.

Energy Content in Chemistry and Physics. By F. WALD (*Zeit. physikal. Chem.*, 8, 272—277).—A criticism of a former paper by Meyerhoffer (this vol., p. 975). The author objects to the method of decomposing energy into the two factors of content and potential, as not applicable to all forms of energy. The assumptions made in the thermodynamical portion of Meyerhoffer's paper are also shown to be untenable.

H. C.

Glass Air Pump. By M. STUHL (*Ber.*, 24, 2542—2543).—The author describes an air pump, made solely of glass, which may be used either for exhausting or compressing, and only requires a water pressure of 1 atmosphere to work efficiently. For details of construction, reference may be made to the sketch in the original paper.

H. G. C.

Universal Gasholder. By EICHORN (*Zeit. anal. Chem.*, 30, 446—450).—The special feature of this gasholder is a tap, H (the construction of which is not described), which can be adjusted to five different positions. The nozzle A is to be permanently connected to a water supply giving a pressure of at least 1 metre of water. In position *a* of the tap, both inlet and outlet are closed; in position *b*, water can enter and compress the gas; in position *c*, water enters whilst gas issues at the nozzle D; in position *d*, the gas way is open, but that for water closed; and in position *e*, water escapes at E,

while gas enters at D. The apparatus can therefore be used either to supply gas under pressure, or as an aspirator, in which latter case

E should be furnished with a long fall tube. Other patterns are constructed in which the tap H may be near the top of the gas holder, or even at a distance from it. M. J. S.

Lecture Experiment to Demonstrate the Dissociation of Ammonium Chloride. By R. BLOCHMANN and R. BLOCHMANN (*Ber.*, 24, 2765—2766).—A hard glass tube, 120—150 mm. in length and 8—9 mm. in internal diameter, is sealed at one end, and held with the open end uppermost in a perpendicular position by a clamp, a piece of wire gauze, 10 cm. square, having a hole in the centre of such a diameter that it fits the tube tightly, is pushed towards the upper end of the tube as far as the clamp, its object being to protect this portion of the tube from the heating. A small quantity of ammonium chloride (about 0.05 gram) is now introduced, and the lower end of the tube heated with the full flame of a Bunsen's burner in such a manner that the point of the inner zone of the flame lies in the same horizontal plane as the bottom of the tube. If a piece of red litmus paper, moistened with water, be placed within the open end, it becomes blue after about a minute; this may be repeated two or three times, until at length the alkaline reaction is no longer observable; on now applying blue litmus paper, this soon becomes red. A. R. L.

Inorganic Chemistry.

Gravimetric Composition of the Air. By A. LÉDUC (*Compt. rend.*, 113, 129—132).—The author has previously shown that the gravimetric composition of the air, as determined by Dumas and Boussingault, does not agree with that calculated from Regnault's values for the sp. gr. of oxygen and nitrogen respectively (*Abstr.*, 1890, 1370). The author has made new experiments, using Brunner's method.

Long, thin sticks of pure phosphorus were introduced into a glass flask of 2—3 litres capacity, and the flask was rendered vacuum and weighed, the residual pressure having been previously measured. Air was then allowed to enter slowly, being dried and purified by passing over potassium hydroxide and phosphoric anhydride. After 24 hours the balloon was again weighed. It was again rendered vacuum, the residual pressure measured, and the flask afterwards weighed. The difference between the first and second weighings gives the total weight of the air, and the difference between the first and third weighings gives the weight of the oxygen. Great care was taken to allow the flask to attain a state of equilibrium before making the weighings, and corrections were made for the difference in residual pressure, the contraction of the flask when made vacuum, and the small quantity of gas in the tube of the stop-cock. Two experiments gave respectively 23·244 and 23·203 per cent. of oxygen, the mean being 23·23.

C. H. B.

Specific Gravities of Oxygen, Hydrogen, and Nitrogen. By A. LÉDUC (*Compt. rend.*, 113, 186—189).—The author has redetermined the relative densities of hydrogen, oxygen, and nitrogen, using a glass flask furnished with a glass stop-cock and an improved manometer, and taking special precautions to prevent errors from the wiping of the flask, &c. Correction was also made for the contraction of the flask when rendered vacuum. The results obtained are as follows:—

	Density. Air = 1.	Weight of 1000 c.c.
Hydrogen	0·0695	0·08984
Oxygen	1·1050	—
Nitrogen	0·9720	—
Air	1·0000	1·2633

The composition of air, calculated from the sp. gr. of its constituents, is oxygen 23·235 per cent. by weight, and 21·026 per cent. by volume, results which agree well with those determined directly.

Regnault's result for the weight of a litre of air, when corrected for the contraction of the flask, is 1·2934, but the separate determinations are less concordant than those of the author (compare preceding abstract).

C. H. B.

A Property of Sulphur. By C. LEPIERRE (*Bull. Soc. Chim.* [3], 5, 308).—When fused sulphur, at 115° or thereabouts, is poured on a printed surface, on cooling, the impression is found imprinted on the surface of the sulphur which has been in contact therewith.

T. G. N.

Purification of Carbon Bisulphide. By A. CHENEVIER (*Chem. Centr.*, 1891, ii, 148; from *L'Union pharm.*, 33, 204).—The unpleasant odour of carbon bisulphide may be entirely removed by the following process:—To 1 litre of carbon bisulphide, 0.5 c.c. of bromine is added and allowed to remain for 3–4 hours. The bromine is then separated again by shaking the carbon bisulphide with a slight excess of potash, or by means of copper turnings. The carbon bisulphide may now be opalescent, but this is readily removed by agitating it with a little potassium chloride, when the filtered bisulphide will be obtained clear, colourless, and of agreeable odour. It leaves no residue on evaporation.

J. W. L.

Isomorphism of Sulphur, Selenium, and Tellurium. By W. MUTHMANN (*Zeit. physikal. Chem.*, 8, 396–397).—With reference to Retgers' suggestion (this vol., p. 1152), that tellurium is not isomorphous with sulphur and selenium, but rather with the platinum metals, the author points out that metallic tellurium is isomorphous with one form of selenium, and thinks the coincidence of form with osmiridium, etc., fortuitous.

J. W.

Phosphorus Trifluorodichloride. By C. POULENC (*Compt. rend.*, 113, 75–78).—Two half-litre flasks, provided with leading tubes from the upper and lower parts, and filled with chlorine and phosphorus trifluoride respectively, are connected in such manner that the fluoride can be displaced by mercury into the upper part of the chlorine flask. The gases contract to half their original volume, according to the equation $\text{PF}_3 + \text{Cl}_2 = \text{PF}_2\text{Cl}_2$, so that the operation is complete when the whole of the fluoride has been transferred. The mixture is left alone for some days; it must not be shaken with mercury, as it is slowly attacked by it even in the cold.

Phosphorus trifluorodichloride thus prepared is a colourless, non-flammable gas, having a sharp, irritating odour. It is instantaneously absorbed and decomposed by water and alkalis. Its vapour density is 5.40, the theoretical number being 5.46. It liquefies under ordinary pressure at -8° . It is decomposed by heat (250°) or electric sparks into phosphorus pentafluoride and pentachloride. Sulphur acts on it at 115° , forming sulphur chloride, and a new gaseous compound, *phosphorus sulphofluoride*, PF_2S , which has a disagreeable odour, is rapidly absorbed by alkalis, and in contact with water, splits up quantitatively into hydrogen phosphate, fluoride, and sulphide. When phosphorus is heated with the fluorochloride at 120° , it decomposes it, forming phosphorus trifluoride and trichloride. It is entirely absorbed by sodium. Magnesium, aluminium, iron, nickel, lead, tin, and mercury attack it at 180° , forming metallic chlorides, and liberating phosphorus trifluoride. Water in small quantity de-

composes it, according to the equation $\text{PF}_3\text{Cl}_2 + \text{H}_2\text{O} = \text{PF}_3\text{O} + 2\text{HCl}$; if a larger quantity is used, the oxyfluoride is decomposed, according to the equation $\text{PF}_3\text{O} + 3\text{H}_2\text{O} = \text{H}_3\text{PO}_4 + 3\text{HF}$. Ammonia reacts with it to form *fluorophosphamide*, $\text{PF}_3(\text{NH}_2)_2$, a light, white solid, soluble in water. JN. W.

Arsenious Oxide Solutions. By E. G. CLAYTON (*Chem. News*, 64, 27).—By agitating arsenious oxide with water at 15° at intervals of half an hour for 4 hours, at intervals of 20 minutes for 6 hours, or at frequent intervals during 4 days, solutions containing respectively 0.118, 0.269 (sp. gr. 1.0023), or 0.99 per cent. of the oxide were obtained. A solution containing 2.22 per cent. was obtained by boiling the oxide with water for an hour and leaving the mixture for 29 hours, but by continuing the boiling for 4 hours the solution at 93° contained 9.52 per cent., and on cooling, after $1\frac{1}{2}$ hours, 8.24 per cent.; after $45\frac{1}{2}$ hours, 3.28 per cent. (sp. gr. 1.0254); after 90 hours, 3.21 per cent., the arsenious oxide being deposited in a finely-divided, crystalline state. Boiling arsenious oxide with 10 per cent. aqueous potassium hydroxide for 3 hours yielded a hot solution containing 34.08 per cent., which, in 24 hours, had deposited crystalline arsenious oxide, retaining 14.29 per cent. in solution. D. A. L.

Boron Phosphide. By A. BESSON (*Compt. rend.*, 113, 78—80).—Boron bromide unites with hydrogen phosphide at ordinary temperatures to form a light, white, amorphous solid, having the composition BBr_3PH_3 . This substance fumes abundantly in the presence of moisture, is violently decomposed by water, with evolution of hydrogen phosphide, and ignites spontaneously in air. It can be sublimed in a closed vessel, or in a current of inert gas, and condenses in small, highly refractive crystals. At 300° , it splits up into hydrogen bromide and boron phosphide, thus giving a convenient way of preparing the latter substance.

Boron phosphide thus obtained is a brown solid, insoluble in water, but soluble in boiling concentrated alkalis, with evolution of hydrogen phosphide. It burns in air, takes fire when projected into cold chlorine, and is attacked by bromine and iodine vapour; strong nitric acid destroys it, the mass becoming incandescent, and even the dilute acid dissolves it with avidity. It gives off hydrogen phosphide, when heated with soda-lime, and phosphorus, when raised to a red heat in a current of hydrogen; in the latter case the residue contains both phosphorus and boron, which seems to point to the existence of a second, more stable combination of these elements. When heated to redness in a stream of nitrogen, boron phosphide gives off phosphorus, and apparently absorbs nitrogen, for when the residue is heated with soda-lime, ammonia, as well as hydrogen phosphide, is obtained.

JN. W.

Silicon Chloriodides. By A. BESSON (*Compt. rend.*, 112, 1314—1316).—The three silicon chloriodides are formed when vapour of iodine chloride is passed over crystallised silicon heated nearly to redness. SiCl_4I boils at 113 — 114° ; SiCl_3I_2 boils at 172° ; and

SiCl_2 , melts at 2° , boils at $234\text{--}237^\circ$, and rapidly becomes coloured when exposed to the air.

Iodine bromide seems to yield silicon bromiodides under similar conditions, but a large quantity of iodine is set free.

Sulphur chloride under similar conditions yields silicon chloride and free sulphur, but at a bright-red heat silicon chlorosulphides are formed; these are under investigation. C. H. B.

Silicon Bromiodides. By A. BESSON (*Compt. rend.*, 112, 1447—1449).—Silicobromoform, when heated in a sealed tube at $200\text{--}250^\circ$ with iodine, yields the bromiodide SiBr_3 ; a small quantity of higher substitution products is formed at the same time.

Dry hydriodic acid acts on silicon bromide at a little below a red heat, giving substitution products, the main constituent being SiI_3 ; the yield is small.

Bromine moniodide, when distilled over crystalline silicon, maintained at nearly a red heat, yields the three possible bromiodides, together with some silicon bromide and iodide. The product may be decolorised by fractionation over copper. The separation of the bromiodides is very difficult. Silicon bromiodides colour rapidly in the air; they absorb dry ammonia gas with the production of white, solid compounds decomposed by water. Silicon bromide in which much iodine has been dissolved may be used in place of the iodine bromide; with the chloride, no reaction occurs.

The bromiodide SiBr_3 is a colourless liquid, distilling at 192° ; it may be cooled to -20° without solidifying, but, when solid, melts at 14° . The bromiodide SiI_2Br_2 is a white solid, which melts at about 38° , and distils at $230\text{--}231^\circ$. The remaining compound, SiI_3Br , is also a white solid, melts at 53° , and distils at 255° ; it is difficult to separate from silicon iodide. W. T.

Silicon Selenide. By P. SABATIER (*Compt. rend.*, 113, 132—133).—When crystallised silicon is heated to redness in a current of dry hydrogen selenide, it is converted into silicon selenide, without incandescence, at a temperature below the boiling point of selenium. The selenide has the composition SiSe_2 , and, after fusion, is a hard, lustrous mass, of semi-metallic appearance. Cold water decomposes it with evolution of hydrogen selenide and separation of silica, but after a time decomposition slackens, and, although it is accelerated on warming, the silicon selenide is never completely decomposed, probably because it is protected by the silica that separates. With potassium hydroxide solution, which dissolves both the hydrogen selenide and the silica, decomposition becomes complete after some time. Aqua regia acts gradually on the selenide with separation of hydrated silica. Under ordinary conditions, silicon selenide evolves a very irritating odour, due, doubtless, to the hydrogen selenide formed by the action of the moisture in the atmosphere. At a red heat in a current of air or dry oxygen, the selenide is converted into silica, selenious anhydride, and selenium. C. H. B.

Carbon Tetriodide. By H. MOISSAN (*Compt. rend.*, 113, 19—22).

—Carbon tetrachloride reacts with boron iodide, BI_3 (this vol., p. 979), to form carbon tetriodide and boron chloride. The tetrachloride, which should be free from chloroform to avoid the formation of iodoform, is best heated in excess with crystals of boron iodide in a sealed tube at 90° for an hour; the tetriodide separates after a time in theoretical quantity, forming fine crystals, which, after washing with sodium hydrogen sulphite solution to remove adherent traces of iodine, are red in colour, and after slow sublimation in a vacuum at 100° , resemble artificial rubies in lustre and shade.

Heated at 140° in a current of hydrogen, carbon tetriodide is reduced to iodoform. It is attacked by chlorine, with the formation of carbon tetrachloride and the chlorides of iodine. Warmed gently in dry oxygen, it is decomposed into iodine and carbon. It reacts violently with fused sulphur, iodine and carbon being set free, and an unspecified compound of sulphur and iodine being formed; if, however, it is heated to 50° with powdered sulphur, carbon bisulphide and sulphur iodide are produced. Phosphorus acts energetically on it. When ground in a mortar with potassium or sodium, the mass becomes incandescent, carbon is liberated, and the alkali iodide is formed; mercury and powdered silver also attack it. Heated with water at 50° , in a sealed tube from which the air has been removed, it slowly decomposes. Hydrogen chloride and iodide have no action on it in the cold, but when heated with it, reduce it to iodoform and liberate iodine.

JN. W.

Action of Light on Silver Chloride. By GUNTZ (*Compt. rend.*, 113, 72—75; compare Hitchcock, *Abstr.*, 1890, 213; this vol., p. 1155; Richardson, *Trans.*, 1891, 536).—When silver chloride, spread in thin layers upon glass slips, is exposed to light, there is at first no darkening or loss of weight, but if it is treated at this stage with a photographic developer, such as ferrous oxalate, it is reduced to the metallic state, showing that a modification has taken place in its constitution. A similar modification is stated to be brought about by boiling silver chloride with water in a reflux apparatus in the dark for some hours.

The disengagement of chlorine may be rendered evident by concentrating a beam of sunlight on the chloride. The residual product in the early stages of the action is stated to be silver subchloride, Ag_2Cl , identical with that prepared from the subfluoride; if treated with ammonia or potassium cyanide, metallic silver is left, but dilute nitric acid does not dissolve it. The author states that he has found that the formation of this subchloride from the chloride is attended with absorption of heat = 28.7 cal., and considers that this explains the increased rapidity of the action when substances capable of absorbing chlorine and giving up heat are present. Silver subchloride, prepared in either of the above ways, is decomposed by the further action of light into silver and chlorine.

Since both the metal and its subchloride are opaque, the final product of the action of light on a layer of silver chloride usually consists of an upper layer of metallic silver, an intermediate layer of subchloride, and a lower layer of unchanged chloride.

JN. W.

Silver Fluoride. By H. MOISSAN (*Bull. Soc. Chim.* [3], 5, 456—458).—A solution of well-washed silver carbonate in hydrofluoric acid is evaporated to dryness, with constant stirring, in a platinum basin, and the resulting black, pulverulent mass is dissolved in water and filtered. The clear filtrate, which, when left in contact with silver foil, yields crystalline silver subfluoride (compare Abstr., 1890, 1055), is evaporated in the dark in a vacuum over sulphuric acid. As thus obtained, silver fluoride forms a yellow, transparent, tough, elastic mass, which is soluble in water, and melts at a dull-red heat (the temperature as determined by Le Chatelier's thermo-electric method is 435°). Silver fluoride reacts violently with the chlorides of phosphorus, silicon, and boron, and with phosphorus oxychloride, yielding the corresponding fluorine compounds of the non-metal and silver chloride. T. G. N.

Electrolysis of Barium Chloride. By C. LINN (*Compt. rend.*, 112, 1434—1436).—The author has been unable to obtain metallic barium by the electrolysis of fused pure barium chloride or of its admixture with sodium chloride.

The electrolyte was contained in a crucible of 500—600 c.c. capacity and a current passed from a small dynamo arranged to maintain a constant difference of potential of 10 volts. The anode consisted of a carbon plate, 5 cm. in length, and was separated by a bottomless, porous cylinder from a wrought iron cathode. The current passing at first was about 30 ampères; with the pure salt, this quickly fell to 2 or 3 ampères, but the original strength was soon regained on agitating the cathode; with the mixture, the electrolysis was regular. In both cases there was an abundant evolution of chlorine. The cathode, when plunged into water, only in a single case gave off a bubble of hydrogen when, according to Faraday's law, there should have been 260 grams of metal. The infusible, non-conducting deposit on the cathode was found to contain considerably less chlorine than the amount required by the barium and sodium present to form normal chlorides, when due allowance had been made for a certain amount of free barium oxide. The conclusion was therefore drawn that some subchloride of barium was formed. W. T.

Hardening of Plaster Casts. By M. DENNSTEDT (*Ber.*, 24, 2557—2558).—The method consists in soaking the cast in a solution of silicic acid prepared by means of a dialyser, drying in a warm place, and then soaking in a solution of barium hydroxide at $60-70^{\circ}$, and again drying. A hard, compact casting is also obtained by mixing the plaster of Paris with aluminium or zinc hydroxide before casting and afterwards soaking in silicic acid. E. C. R.

Preparation of Crystalline Monocalcium Phosphate. By G. POINTET (*Bull. Soc. Chim.* [3], 5, 254—256).—Neither the crystalline nor the honey-like commercial variety of monocalcium phosphate corresponds with the formula $\text{CaH}_4(\text{PO}_4)_2$, owing to the free sulphuric acid in the crude liquor acting on the phosphate during evaporation. By leaving tricalcium phosphate in contact with

a solution of the honey-like commercial variety for some time, a solution is obtained which, on gentle evaporation, yields crystals of pure monocalcium phosphate. T. G. N.

Action of Acetates on Monocalcium Phosphate. By H. CAUSSE (*Bull. Soc. Chim.* [3], 5, 298).—If monocalcium phosphate (50 grams) is dissolved in water, and glacial acetic acid (25 grams) added to the filtered solution, the subsequent addition of a few c.c. of an alkali acetate solution causes a turbidity, and the deposition after some days of rhomboidal scales of dicalcium phosphate of the formula $\text{CaHPO}_4 + 2\text{H}_2\text{O}$. Similar crystals are obtained when cold saturated solutions of sodium phosphate (1500 c.c.) and calcium chloride (400 c.c.) are mixed with fuming hydrochloric acid (100 c.c.), and a few drops of potassium acetate solution added to the mixture. T. G. N.

Thallium Compounds. By C. LEPIERRE and M. LACHAUD (*Compt. rend.*, 113, 196—198).—A boiling solution of 112 grams of potassium hydroxide per litre can dissolve about 3.5 grams of thallium chromate, which separates on cooling in hexagonal prisms, terminated by hexagonal pyramids. These crystals belong to the rhombic system, so that thallium chromate is isomorphous with potassium sulphate. No basic thallium chromates are obtained similar to those formed by lead chromate.

When thallium chromate is projected into fused potassium hydroxide, soluble potassium chromite, $\text{Cr}_2\text{O}_3 \cdot 3\text{K}_2\text{O}$, and insoluble thallic oxide are formed. The latter remains in the form of hexagonal plates when the product is treated with water; sp. gr. = 5.56. It is insoluble in water, and dissolves with difficulty in sulphuric acid but more readily in hydrochloric acid.

If thallium chromate is fused for a long time with potassium nitrate, a small quantity of thallic oxide is formed, but the greater part of the chromate remains unaltered. If a mixture of thallium and potassium chromates is fused with the potassium nitrate, a crystallised double chromate, KTlCrO_4 , is obtained. Lead chromate does not combine with thallium chromate.

When freshly prepared thallous chloride is treated with a highly concentrated solution of 20 parts of chromic acid, crystals of thallium chlorochromate, TlCrO_3Cl , separate. They are small prisms with a square base, and are decomposed by water with formation of thallous chloride and chromic acid. C. H. B.

Copper Hydrides. By A. LEDUC (*Compt. rend.*, 113, 71—72).—On passing a stream of hydrogen for about two hours over a quantity of copper, contained in a combustion tube, heated to cherry-redness at the middle and to 300° at the ends, a solid of a hyacinth-red colour was formed at those parts which had reached, but not exceeded, dull redness, and when these parts were subsequently heated to bright redness in a stream of carbonic anhydride, the escaping gas was found to contain hydrogen, together with a little carbon monoxide. The substance is believed to be a new hydride of copper. JN. W.

Action of Water on Basic Copper Salts. By G. ROUSSEAU and G. TITE (*Compt. rend.*, 113, 191—193).—Basic cupric nitrate, when heated with water in sealed tubes at 160° for 20 hours, is completely converted into black, amorphous cupric oxide, the water becoming strongly acid. The basic nitrate in the dry, solid state only decomposes at about 400° , and Rousseau has shown that it can be formed by heating concentrated solutions of cupric nitrate with marble between 180° and 330° .

Basic cupric sulphate is not decomposed by water below 220° , and decomposition is only complete after heating for 150 hours at 240 — 250° . As a rule, the cupric oxide is pseudomorphous after the basic sulphate, but sometimes it forms opaque, elongated prisms.

Atacamite is not affected by water at 200° ; between 200° and 210° it darkens slightly, but at 240° the decomposition is almost complete after 24 hours. At this temperature, however, the oxychloride itself dissociates into the oxide and the chloride, so that the water plays no part except forming a solvent for the chloride.

Basic cupric phosphate is not affected by water at 275° , even after three days.

The decompositions are in accordance with thermochemical data, the reaction being determined at a moderately high temperature by the increase in the heat of solution of the liberated acid. The progress of the decompositions resembles the saponification of ethereal salts, as already observed by Saint Gilles in the case of ferric acetate.

C. H. B.

Copper Phosphates. By J. STRINSCHNEIDER (*Chem. Centr.*, 1891, ii, 51—52; *Dissertation, Halle*, 1890).—The author has obtained the following copper phosphates by the action of disodium hydrogen phosphate on copper sulphate:—

a. By employing an excess of copper sulphate, a double salt of the formula $3\text{Cu}_3\text{P}_2\text{O}_8\cdot\text{Na}_2\text{H}_2\text{PO}_4$ is formed; if the copper sulphate be present in very large excess, Rammelsberg's normal phosphate, $\text{Cu}_3\text{P}_2\text{O}_8$, is formed. Both these salts, if subjected to protracted washing under pressure, are converted into the compound $4\text{CuO}\cdot\text{P}_2\text{O}_5$, already described by Debray, Sarrazin, and Friedel. Sodium acetate precipitates the double salt $3\text{Cu}_3\text{P}_2\text{O}_8\cdot\text{Na}_2\text{C}_2\text{H}_3\text{O}_7$ from the filtrate.

b. By employing an excess of sodium phosphate, two double salts are formed, namely, $2\text{Cu}_3\text{P}_2\text{O}_8\cdot\text{Na}_2\text{HPO}_4$ and $3\text{Cu}_3\text{P}_2\text{O}_8\cdot\text{Na}_2\text{H}_2\text{PO}_4$; the former is formed first and is converted into the latter by continued washing.

By the action of disodium hydrogen phosphate on cupric chloride, the following phosphates are formed:—

a. When an excess of cupric chloride is employed, the double salt $3\text{Cu}_3\text{P}_2\text{O}_8\cdot 2\text{NaCl}$ is principally formed, although sometimes it is mixed with the phosphate, $4\text{CuO}\cdot\text{P}_2\text{O}_5$, and the oxychloride, $\text{CuO}\cdot\text{CuCl}_2$; in one case the salt had the formula $5\text{Cu}_3\text{P}_2\text{O}_8\cdot 3\text{NaCl}$.

b. If an excess of the sodium phosphate is employed, the same phosphate, $3\text{Cu}_3\text{P}_2\text{O}_8\cdot 2\text{NaCl}$, is formed as in the case of employing an excess of cupric chloride.

By the action of the sodium phosphate on cupric nitrate, the following phosphates are obtained:—

a. By employing a slight excess of the cupric nitrate, the double salt $\text{Cu}_3\text{P}_2\text{O}_8 \cdot \text{Na}_2\text{H}_2\text{PO}_4$ is formed, whilst if the cupric nitrate is present in very large excess, the normal phosphate, $\text{Cu}_3\text{P}_2\text{O}_8$, together with a small quantity of basic cupric nitrate is obtained.

b. If the sodium phosphate is employed in excess, a double salt of the formula $18\text{CuO} \cdot 3\text{Na}_2\text{O} \cdot 8\text{P}_2\text{O}_5$, or $6\text{Cu}_3\text{P}_2\text{O}_8 + 3\text{Na}_2\text{O} \cdot \text{P}_2\text{O}_5$, is formed, which is decomposed by washing.

The basic phosphate, $4\text{CuO} \cdot \text{P}_2\text{O}_5$, with 1 mol. H_2O , is obtained by washing the normal phosphate, $\text{Cu}_3\text{P}_2\text{O}_8$, and corresponds with the mineral libethenite. If boiled with silver nitrate, it remains unchanged, whilst the normal cupric phosphate is quantitatively converted into cupric nitrate under similar conditions. With ammonia or ammonium carbonate, the basic phosphate dissolves very slowly, whilst cupric phosphate is readily dissolved by these reagents. Barium hydroxide decomposes the normal phosphate, but does not react with the basic phosphate. Potassium iodide reacts with the normal phosphate but not with the basic phosphate. Sodium thiosulphate dissolves the normal phosphate at ordinary temperatures, but the basic phosphate is only dissolved at a boiling heat.

If copper carbonate is warmed at 70° with phosphoric acid, the salt $3\text{CuO} \cdot \text{P}_2\text{O}_5 + 3\text{H}_2\text{O}$ is obtained, whilst if the carbonate is neutralised with phosphoric acid, an acid salt, $\text{CuO} \cdot \text{P}_2\text{O}_5$, is found in the filtrate. Whilst the phosphates of copper show, generally, a great similarity to the copper arsenates (this vol., p. 644), the phosphates corresponding with the arsenates $8\text{CuO} \cdot 3\text{As}_2\text{O}_5$ and $5\text{CuO} \cdot 2\text{As}_2\text{O}_5$ have not been prepared, and only the normal copper phosphate and double salts are obtained. On the other hand, whilst the normal phosphate is readily prepared by employing an excess of the reacting copper salt, the normal arsenate was obtained with difficulty.

J. W. L.

Erbium and Didymium. By G. KRÜSS (*Annalen*, 265, 1—27).—It has been shown by Marignac, Soret, Nilson, Cleve, and Brauner that erbium earth, which, about 15 years ago, was considered to be the oxide of the element erbium, consists of at least seven different substances, namely, of scandium, ytterbium, thulium, erbium, terbium, the ytterite earth, and those earths denoted with X by Soret. The more recent researches of Lecoq de Boisbaudran have afforded evidence which proves that Soret's X-earth, or Cleve's holmium, consists of at least two elements, whilst Crookes' investigations have shown that the ytterite earth is composed of more than one oxide. The substance previously known as didymium has also been found to be a compound and to consist of samarium and the real didymium; according to Auer von Welsbach, the last-named substance consists of at least two "elements," neo- and praseo-didymium, both of which are probably compounds, as has been shown by Krüss and Nilson.

The author has made a number of experiments, with the object of isolating some of the constituents of the erbium and didymium groups, employing the best known methods; although it is possible in this way to obtain preparations in the spectra of which the relative intensities of the absorption lines are quite different from those usually observed, absolutely pure substances, whose molecular weights remain

constant on further treatment, could not be obtained. Several new methods of separation have, therefore, been studied, and the older processes have also been subjected to a more rigorous examination; the results are given below.

The separation of the erbium and didymium earths can be partially effected by fractional crystallisation with potassium hydrogen sulphate; although in this way the didymium is accumulated in the first, and the erbium earths in the last, fractions, a complete isolation of the former was found to be impossible. Experiments were then made to try and separate the didymium by fractional precipitation with ammonia; for this purpose, a large quantity (rather more than 1 kilo.) of the mixed oxides obtained from gadolinite from Hitterö and Ytterby, was first freed from iron and some cerium, and then a neutral solution of the nitrates submitted to a systematic fractional precipitation with dilute ammonia. The spectrum of a concentrated solution of the nitrate of the didymium oxide obtained in this manner from the last fractions showed no erbium bands, and the nitric acid solution of the first fractions was quite free from didymium. The earths were, however, in both cases, mixed with colourless oxides, the didymium being probably accompanied by lanthanum, samarium, yttrium, and terbium, and the erbium by holmium, thulium, scandium, ytterbium, and cerium, assuming that all these substances were present in the original material. In order to prepare pure didymium oxide from the impure compound obtained as just described, it is first converted into the nitrate, the solution mixed with a large excess of soda, and then treated with chlorine, when the hydroxides of didymium, lanthanum, and of the colourless earths pass into solution, whilst the undissolved cerium hydroxide retains only a small quantity of didymium; the filtrate is then freed from chlorine, the earths precipitated with ammonia, and converted into nitrates. The almost neutral solution is now treated with potassium sulphate; the crystalline precipitate contains, besides didymium, some samarium and perhaps scandium and lanthanum, whilst yttrium and traces of samarium, erbium, terbium, and ytterbium, if present, pass into the filtrate; in the actual experiment, the filtrate seemed to contain principally yttrium and a small quantity of terbium. After repeating the treatment with potassium sulphate, the didymium potassium sulphate is precipitated with ammonia, the washed precipitate dissolved in sulphuric acid, and the anhydrous sulphate dissolved in ice-cold water; on gradually heating this solution, no separation of lanthanum sulphate occurred, so that the preparation evidently consisted of pure didymium sulphate. The atomic weight of the didymium present in this salt was found to be $R^{III} = 145$; its isolation from gadolinite in the manner described is a comparatively simple matter.

When a neutral solution of the chlorides of erbium, ytterbium, and yttrium in 50 per cent. alcohol is mixed with excess of a solution of aniline in the same solvent at 0° , no precipitation occurs; when, however, the mixture is kept for some time until it attains the ordinary temperature, a precipitate is gradually formed. In this way the various components of the solution can be partially separated from one another, as is shown by the fact that when a solution of a mixed

oxide, $R^{III} = 161.81$, is subjected to this treatment, a precipitate, $R^{III} = 168.75$, and a filtrate containing an oxide, $R^{III} = 158.38$, are obtained.

When a neutral solution of the mixed gadolinite earths is treated with a concentrated solution of ammonium carbonate, kept for 24 hours, filtered, and the residue washed with ammonium carbonate, the precipitated basic didymium carbonate is almost free from erbium earths; on passing a stream of air through the filtrate, basic carbonates of the erbium earths, containing only a small quantity of didymium, are precipitated.

A partial separation of the didymium and ytterite earths can be effected by treating a solution of the mixed nitrates with a concentrated solution of potassium oxalate, digesting for 24 hours, and then filtering; the residue shows only slight indications of erbium lines on spectroscopic examination, and consists principally of didymium and holmium, whilst the filtrate is almost free from didymium, but contains considerable quantities of erbium and yttrium or scandium. When this filtrate is evaporated to dryness, ignited, and the residue extracted with water, a solution of scandium, containing only a little erbium, and probably also traces of didymium, is obtained.

By fractionally precipitating with alcohol, a neutral solution of the nitrate of the didymium ($R^{III} = 144-145$), obtained as described above, a nitrate of a colourless earth, which is insoluble in alcohol, is precipitated; atomic weight determinations made with a carefully purified sample of this earth gave $R^{III} = 111.6$ as the average of three experiments, and this value underwent no appreciable change on continuing the fractional precipitation with alcohol.

F. S. K.

Melting Point and Crystalline Form of Aluminium Chloride.

By K. SEUBERT and W. POLLARD (*Ber.*, 24, 2575—2578).—The aluminium chloride was prepared by heating aluminium foil in a current of dry hydrogen chloride, and was quite white. The resublimed product melts at $193-194^{\circ}$, but sublimes and seems to boil at $175-179^{\circ}$. When heated in a closed tube at 200° , it is obtained, on cooling, in colourless, lustrous, six-sided tablets, which adhere to the walls of the tube. These crystals are mostly composed of three individuals twinned together, and show rhombic symmetry. The positions of extinction are 120° from one another. The apparent angle of the optic axis in air is about 12° . The crystals are optically negative.

E. C. R.

Action of Nitric Acid on Iron. By H. GAUTIER and G. CHARPY (*Compt. rend.*, 112, 1451—1453).—At the ordinary temperature, perfectly clean iron placed in nitric acid of specific gravity greater than 1.21 does not give any disengagement of gas; it is, however, slowly attacked, with formation of iron nitrate, traces of ammonia, and nitrogen peroxide, which remain in solution. The nitric acid which has been in contact with iron for some time gives a precipitate on neutralisation with potash. The following table shows the effect of acid of different concentrations on the weight of a piece of iron at the ordinary temperature:—

Acid of specific gravity.....	1.28; 1.34; 1.38; 1.48; 1.53
Percentage loss of weight for 24 hours during	<div> <div>(1) first two days....</div> <div>(2) first ten days....</div> </div>
	0.82; 0.75; 0.29; 0.34; 5.80
	0.59; 0.45; 0.25; 0.33; 5.75

The E.M.F. of an iron | platinum | nitric acid cell diminishes rapidly as the strength of the acid increases from a sp. gr. below 1.21 to higher densities. In the latter case, it is about 0.15 volt, and corresponds with solution of the iron, for, with circuits of different resistances, different intensities are obtained. By raising the temperature, the limit of specific gravity of the acid giving disengagement of gas and rapid attack is raised. At 60° it is only with concentrations above 1.38 that no disengagement of gas occurs. The limit is also raised by the presence of oxide on the surface of the iron; this is due to local heating caused by the solution of the oxide. If the iron be agitated in the acid until perfectly clean, it then behaves exactly as if the surface had not been coated with oxide. The same effect is produced if the oxide be electrolytically reduced.

The passive state of iron cannot be due to the production of a film of gas or of oxide upon the surface of the iron, but is probably produced by fuming nitric acid, owing to the modification which the latter causes in the oxide of iron, by which the oxide is rendered insoluble in the acid.

This modification probably consists in a dehydration, for if rusty iron be heated for some time at 140°, the acid of ordinary concentration no longer dissolves it with evolution of gas.

Nitric acid, whatever its concentration may be, attacks iron. The attack may be rapid and accompanied by evolution of gas, or, as is the case in the so-called passive state of iron, it may be slow and without disengagement of gas.

W. T.

A Volatile Compound of Iron and Carbonic Oxide. Nickel-carbon-oxide. By BERTHELOT (*Compt. rend.*, 112, 1343—1349).—Finely-divided iron is obtained by reducing carefully washed and dried, precipitated ferric oxide in hydrogen at the lowest possible temperature, or by heating ferrous oxalate and completing its reduction in hydrogen.

The reduced iron is treated with carbonic oxide at about 45°, when the gas becomes charged with a volatile iron compound. The charged gas is washed and burnt at the drawn-out extremity of a glass tube; the flame is whiter and brighter than that of carbonic oxide alone, and gives a characteristic spectrum. When a porcelain dish is held in the flame, a film is deposited, which dissolves in hydrochloric acid, yielding a solution which gives the ordinary iron reactions. The gas, when passed through a narrow glass tube heated to redness, deposits a metallic substance, consisting of iron with a little carbon. The charged gas, when treated with strong hydrochloric acid, yields iron chloride, and when confined in a flask partly filled with aerated water, a slow oxidation takes place, ferric oxide separating at the end of several days. The proportion of iron-carb-

oil formed is very small, and the author did not succeed in isolating it (compare Mond and Quincke, Trans., 1891, 59, 604).

Nickel-carbon-oxide (Mond, Langer, and Quincke, Trans., 1890, 57, 749).—The liquid substance possesses a high vapour tension at ordinary temperatures; about a quarter of an atmosphere at 16°. It has no sensible dissociation tension at 16°, and a gaseous mixture of nitrogen and the vapour, containing 26 per cent. of the latter, has been kept over mercury for a month at about this temperature without any indication of change. The liquid may be kept unaltered under water, provided the vessel be completely filled with water free from air, and hermetically closed. The detonation observed by Mond, on rapidly heating the vapour, is not violent as compared with that of the nitro-compounds; the products of decomposition include a certain proportion of carbonic anhydride and carbon, as well as of carbonic oxide and nickel. It is this production of carbonic anhydride which determines the decomposition; a simple resolution of the nickel-carbon-oxide into nickel and carbonic oxide would be inexplicable in view of the formation of this substance at 30° by direct synthesis. The decomposition of carbonic oxide into carbonic anhydride and amorphous carbon gives for 12 grams of carbon +38.8 cal. If the heat of formation of $\text{Ni}(\text{CO})_4$ be less than 77.6 cal. by the direct union of nickel and carbonic oxide, explosion could occur by intramolecular combustion; according to the author, if exploded by the shock of an energetic detonator, such as mercury fulminate, the decomposition would occur solely in accordance with the equation $\text{NiC}_2\text{O}_4 = \text{Ni} + 2\text{CO}_2 + 2\text{C}$. With a slower reaction, effected at a lower temperature, more or less nickel-carbon-oxide may be simultaneously decomposed into nickel and carbonic oxide, the heat required being supplied by the portion undergoing intramolecular combustion.

A mixture of the vapour with oxygen or air burns or explodes on contact with a very hot substance, according to the relative proportions of the vapour and oxygen present. The explosion of a mixture of dry nickel-carbon-oxide with oxygen may be brought about by simple energetic agitation over mercury. The same gaseous mixture in presence of a little water oxidises slowly, with formation of a greenish, gelatinous precipitate. This compound contains nickel, oxygen, water, and some combined carbon; it blackens from separation of carbon on heating. Simultaneously with the production of this complex oxide in the cold, carbonic oxide is regenerated. The dry mixture undergoes a similar decomposition, but the oxide formed is yellowish-brown; in time it blackens by further decomposition.

Liquid nickel-carbon-oxide kept under water without exclusion of air decomposes in a similar manner, but more slowly. Nickel-carbon-oxide thus behaves in a manner analogous to the organo-metallic radicles and the metallic derivatives of acetylene.

In contact with concentrated sulphuric acid, dry nickel-carbon-oxide detonates after a few moments. A mixture of the vapour with nitrogen reacts quietly with the same acid, producing nickel sulphate and 4 vols. of carbonic oxide, the acid undergoing reduction. Concentrated potash seems to have no action. Pure ammonia gas

does not act on nickel-carbon-oxide, at least immediately, but if oxygen be gradually added to the mixture, a whitish complex substance, blackening when heated, is deposited.

Hydrogen sulphide rapidly precipitates a black sulphide from the vapour in the cold; hydrogen phosphide similarly causes the deposition of a black, shining compound.

Nitric oxide, passed into liquid nickel-carbon-oxide, or mixed with its vapour volatilised in nitrogen, produces blue fumes, slowly deposited. The addition of a further quantity of nitric oxide, even when its initial volume was four times that of the gaseous nickel-carbon-oxide, reproduces these fumes. The inference is drawn that the vapour of another nickel compound is present as well as the nickel-carbon-oxide, and forms a blue compound immediately with nitric oxide, which is present in excess. If a few bubbles of oxygen be introduced in place of the second quantity of nitric oxide, a blue compound, different from the one noticed above, is formed.

The author calls attention to the part probably played by the compound of iron and carbonic oxide in metallurgical processes, such as Siemens' and the cementation processes, and to the possible explanation afforded of the precipitation of carbon from carbonic oxide by iron, observed by Gruner, and of Cailletet's observations of the formation of gaseous bubbles in the interior of softened iron.

W. T.

Volatilisation of Nickel and Iron in presence of Carbonic Oxide. By J. GARNIER (*Compt. rend.*, 113, 184—191).—Some time ago the author observed the luminosity of the flame of carbonic oxide formed in the manufacture of iron and steel, and the separation of nickel and nickel oxide in the flues of a furnace in which ferro-nickel was heated. He considers that these phenomena were due to the formation of the volatile compounds of iron and nickel with carbonic oxide.

C. H. B.

Volatility of Nickel in presence of Hydrogen Chloride. By P. SCHÜTZENBERGER (*Compt. rend.*, 113, 177—179).—When dry hydrogen is passed over anhydrous nickel chloride heated to dull redness, and the tube through which the gas escapes is heated to dull redness at any point, a white deposit of nickel chloride takes place at that point. The volatile substance is not removed by passage of the gas through glass wool and along a considerable length of tube at the ordinary temperature. Similar results are obtained when hydrogen chloride is passed over finely-divided nickel, and it is evident that a gaseous compound containing nickel is formed. This gas has most probably the composition NiClH , and reacts with hydrogen chloride when heated, in accordance with the equation $\text{NiHCl} + \text{HCl} = \text{NiCl}_2 + \text{H}_2$.

C. H. B.

Cobalt Dioxide. By G. VORTMANN (*Ber.*, 24, 2744—2749).—Pure cobalt sulphate is dissolved in water and treated with decinormal iodine solution and pure soda, at a temperature of 50—60°, the liquid is filtered, the filtrate acidified, and the excess of iodine

determined in the usual manner. As the result of 25 experiments, the composition of the precipitate is found to vary from $\text{Co}_{10}\text{O}_{18.65}$ to $\text{Co}_{10}\text{O}_{19.27}$. It doubtless consists chiefly of *cobalt dioxide*, which is, however, very unstable. Its formation appears to be dependent on a variety of conditions. Cobalt dioxide has a greenish-black colour, and decomposes at 100° . The oxidation of the cobalt is not facilitated by the employment of a more concentrated iodine solution, or by the presence of aluminium, iron, zinc, or magnesium salts. It appears probable that the compound formed by the action of argentic oxide on cobaltous oxide is not represented by the formula $\text{Ag}_2\text{O}, \text{Co}_2\text{O}_3$, as stated by H. Rose, but that it is a mixture of finely divided silver and cobalt dioxide, or the corresponding hydroxide.

J. B. T.

Action of Heat on Solutions of Chromic Salts. Green Salts of Chromium. By A. RECOURA (*Compt. rend.*, 112, 1439—1442).—The author proves, by thermochemical methods, that the green solutions obtained by heating solutions of the normal violet chromic salts contain free acid and a soluble basic salt, and further, that such solutions contain a particular variety of chromic oxide.

A solution of a chromic salt, such as the sulphate or chloride, when heated on a water-bath at 100° , emits acid vapours, whereas the solid salt at the same temperature is not decomposed. The amount of free acid present in the green solution of the sulphate was determined by adding a definite quantity of soda solution, and measuring the heat disengaged; so long as this equalled the heat of neutralisation of free sulphuric acid, there was at least the amount of free acid present equivalent to the soda used. A control to the final result was obtained by adding an equivalent amount of sulphuric acid after the addition of the soda; if no excess of soda were added in the first place, there was merely a slight absorption of heat, due to the action of the acid on the sodium sulphate previously formed.

A large number of experiments, conducted at different degrees of dilution, gave the formula of the soluble basic sulphate as $2\text{Cr}_2\text{O}_3, 5\text{SO}_3$. This salt contains a modified oxide, which cannot exist in the free state; the oxide precipitated from the green solution by alkalis forms, on redissolving, a new basic salt, $\text{Cr}_2\text{O}_3, 2\text{SO}_3$.

W. T.

New Process for the Manufacture of Chromates. By J. MASSIGNON and E. VATEL (*Bull. Soc. Chim.* [3], 5, 371—376).—The author describes the following process, which is based on the fact that when chromium oxide is heated with a mixture of calcium chloride and oxide, a chromite is formed, which absorbs oxygen from the air to yield a calcium chromate. The finely powdered mineral is mixed with a paste composed of lime, calcium carbonate, and a concentrated solution of calcium chloride in such proportion that the lime and calcium carbonate are slightly in excess of the amount necessary to combine with the chromium oxide present, whilst the calcium chloride is about one-third of the total lime used. The mixture, on exposure to air, hardens, and is moulded into bricks, which are dried and subsequently roasted at a temperature

sufficient to convert the calcium carbonate into lime. The bricks are exposed to the action of the air for about a month, then lixiviated with hot water to remove the calcium chloride, and the residue containing the calcium chromate is treated with alkali carbonate or sulphuric acid in the usual way, according as an alkali chromate or chromic acid is required. T. G. N.

Reaction of Chromic Acid with Barium Hydroxide in presence of Oxygen. By E. PÉCHARD (*Compt. rend.*, 113, 39—41).—When a dilute aqueous solution of chromic acid (8 grams per litre) is treated at a low temperature with excess of oxygen dissolved in water, and barium hydroxide is added in slight excess, a precipitate, at first yellowish, but afterwards darker, is thrown down, and oxygen begins to be evolved; if the whole is then poured rapidly into a large excess of water, the precipitate may be collected and dried in a vacuum over sulphuric acid.

The substance thus obtained explodes with a sharp report when heated in a test-tube, leaving a residue which appears to consist of barium chromate mixed with a little barium oxide. With dilute sulphuric acid, it gives a fine blue colour, which, however, soon disappears, with evolution of oxygen. Its composition is represented approximately by the formula BaCrO_5 . J. N. W.

Zirconates of the Alkalis. By L. OUVRARD (*Compt. rend.*, 112, 1444—1446).—Zirconium oxide, when fused with lithium carbonate, rapidly decomposes it with liberation of carbonic anhydride; after six or eight hours fusion over a Bunsen flame, a mass is obtained which, on treatment with boiling water slightly acidified with acetic acid, yields a crystalline powder consisting of zirconium oxide free from lithium. Finely pulverised zircon yields the same result. On substituting lithium chloride for the carbonate, and cooling the fused mass slowly, flat prisms, with longitudinal extinction, often corroded, are obtained on treating it with water. These crystals are readily attacked by acids, and consist of Li_2ZrO_5 .

Crystallised zirconium oxide only is obtained by fusion of the oxide with potassium carbonate. Finely-powdered zircon heated with potassium carbonate to bright redness for 15 minutes yields well developed, tabular crystals of the silicozirconate K_2SiZrO_6 . These are prisms having longitudinal extinction, and are attacked by hydrofluoric acid and by ammonium hydrogen sulphate. If the reaction is prolonged for an hour and a-half at the same temperature, crystallised zirconium oxide alone is obtained. Here zircon silicate behaves like a true acid. A further example will be given among the alkaline earthy combinations to be described. Sodium carbonate yields no compounds. W. T.

Zirconates of the Alkaline Earths. By L. OUVRARD (*Compt. rend.*, 113, 80—82).—When zirconium oxide is fused with calcium chloride at a red heat for 20 or 30 hours, it becomes crystalline; and on extracting the melt with water, optically active, striated crystals

of calcium zirconate, CaZrO_3 , insoluble in acids, and isomorphous with calcium stannate and titanate (perovskite), are left behind.

Strontium and barium zirconates are prepared in a similar manner.

If finely-powdered zircon is substituted for the oxide, and the temperature is raised to a white heat, clean rhombic crystals of calcium silicozirconate, CaSiZrO_6 , are obtained, isomorphous with artificial sphene and calcium silicostannate.

JN. W.

Antimony Pentasulphide. By T. WILM (*Zeit. anal. Chem.*, 30, 428—446).—Preparations passing under the name of "Golden Sulphide of Antimony (Goldschwefel)," and having a composition agreeing with the formula Sb_2S_5 , but from different makers, give very varying results when used in the vulcanisation of caoutchouc. In the course of a study of two such samples, the author has prepared the so-called antimony pentasulphide of the text-books by the following methods:—(1) By mixing a solution of sodium thioantimonate (Schlippe's salt) with a slight excess of dilute sulphuric acid; (2) by precipitating with hydrogen sulphide a clear solution of potassium antimonate under various conditions, (a) alone, (b) after addition of tartaric acid, (c) of both tartaric acid and a small quantity of hydrochloric acid, (d) of tartaric acid and a large quantity of hydrochloric acid; in case c the precipitation was performed in two fractions; (3) by passing hydrogen sulphide through an aqueous solution of commercial antimony trichloride, which had first been saturated with chlorine, then warmed on the water-bath until the odour of chlorine had disappeared, and mixed with tartaric acid; (4) by the action of hydrogen sulphide on a solution (mixed with tartaric acid) of commercial antimony pentachloride. Preparation 1 when dry formed dense, hard, brittle, dark-brown grains; those thrown down by hydrogen sulphide were loose, bulky, soft, orange-yellow masses. The composition of these preparations and their behaviour when treated with carbon bisulphide are shown in the following table. Preparation 1 had been dried in the desiccator; the others by heat:—

	Preparation.								Commercial products.	
	1.	2a.	2b.	2c, 1st fraction.	2c, 2nd fraction.	2d.	3.	4.	A.	B.
Total sulphur....	40.7	38.1	39.0	39.8	37.1	39.4	41.3	38.6	41.9	40.4
Sulphur extracted by CS ₂	7.9	13.9	11.7	12.2	8.2	8.4	6.4	13.8	13.3	8.9
Difference.....	32.8	24.2	27.3	27.6	28.9	31.0	34.4	24.8	28.6	31.5

Since Sb_2S_5 contains 39.58 and Sb_2S_3 28.23 per cent. of sulphur, it will be seen that the composition of the original preparation varied somewhat considerably from that of the pentasulphide, whilst that of

the residue varied still more widely, the sulphur extracted being in three cases more than would agree with the original existence of a mixture of the composition $\text{Sb}_2\text{S}_3 + \text{S}_2$. Preparation A invariably gave good results in vulcanising; B, on the contrary, bad results; the technical method of judging of the value of a preparation from an estimation of the sulphur which it gives up to carbon bisulphide seems therefore by no means trustworthy.

A property of the pentasulphide hitherto unnoticed is its volatility and oxidation even at 100° . Preparation 1, which, after drying in the desiccator, gave up no antimony to tartaric acid, lost weight considerably during 15 hours at 120° , continued thereafter to lose at 100 — 110° , and subsequently gave up antimony to tartaric acid.

To ascertain the influence which the above facts would have on Bunsen's method of separating arsenic and antimony by precipitating the latter as pentasulphide from the oxidised solution, washing with water, alcohol, carbon bisulphide, and again alcohol, drying at 110° , and weighing as pentasulphide, a preparation was made according to Bunsen's instructions, with the exception that tartaric acid was added to dissolve a white precipitate which separated whilst passing chlorine. During the washing with water, much of it assumed a colloidal form, and refused to subside. After washing with water and alcohol only, it was divided into two portions, one of which was without drying treated with carbon bisulphide. It gave up a considerable quantity of pure sulphur. After drying over sulphuric acid in the cold, it contained 39.96 per cent. of sulphur, of which 3.59 per cent. was soluble in carbon bisulphide. Preparations by method 1 likewise gave up sulphur to carbon bisulphide before drying. It appears, therefore, that accurate results cannot be obtained by Bunsen's process.

M. J. S.

Action of Phosphorus Pentafluoride on Heated Spongy Platinum. By H. MOISSAN (*Bull. Soc. Chim.* [3], 5, 454—456; compare Abstr., 1886, 592).—When phosphorus pentafluoride acts on pure platinum sponge at a temperature slightly above dull redness, a volatile, crystalline compound condenses in the cooler portion of the tube; this has the formula $\text{PF}_3\cdot\text{PtF}_5$, analogous to the compound $\text{PCl}_3\cdot\text{PtCl}_2$ discovered by Schützenberger.

T. G. N.

Osmium: Osmiamic Acid and Osmiamates. By A. JOLY (*Compt. rend.*, 112, 1442—1444).—*Preparation of Potassium Osmiamate.*—100 parts of osmium tetroxide is dissolved in 100 parts of potash with 50 parts of water; the solution is kept at about 40° and 40 c.c. of ammonia solution added. In a short time, the brown liquid is decolorised, and a clear, yellow, crystalline precipitate of potassium osmiamate is deposited; it recrystallises from its solution in boiling water in fine, quadratic octahedra.

The reaction is not accompanied by any escape of gas. Taking the atomic weight of osmium as 190, the formula KNOsO_3 agrees better with the results obtained by Fritzsche and Struve (*Bull. Acad. St. Pétersbourg*, 6, 81) than that proposed by them, $\text{K}_2\text{N}_2\text{Os}_2\text{O}_5$; this is supported by the author's determinations of potassium and nitrogen,

and by the non-formation of a gas, $\text{OsO}_4 + \text{KOH} + \text{NH}_3 = \text{KNOsO}_3 + 2\text{H}_2\text{O}$.

Heated in a vacuum above 200° , potassium osmiumate is rapidly decomposed with evolution of nitrogen. At 440° , nearly the whole of the nitrogen is eliminated. The solid products of the decomposition differ according to the temperature employed; at 350° , potassium osmite and osmium dioxide remain; at 440° , an indigo-blue, crystalline substance is formed; it is insoluble in water, and is scarcely attacked by concentrated hydrochloric acid; its composition is represented by the formula KOsO_3 . This salt would correspond with an acid HOsO_3 and an oxide Os_2O_5 ; the study of these compounds will be followed up in view of the known existence of a ruthenium oxide Ru_2O_5 . Osmiamic acid, $\text{OsNO}_3\cdot\text{OH}$, may be viewed as a first anhydride of $\text{OsNO}(\text{OH})_2$, the hypothetical analogue of the nitroso-compounds of ruthenium, RuNOCl_2 and $\text{RuNO}(\text{OH})_2$, previously described. W. T.

Mineralogical Chemistry.

Native Iron of Terrestrial Origin from Berezowsk. By DAUBRÉE and S. MEUNIER (*Compt. rend.*, 113, 172—177).—Two specimens, weighing respectively 11.5 and 72.0 grams, were found in the auriferous deposits at Berezowsk, in the Ural, near Ekaterinbourg. They have evidently been subjected to great pressure and a contorting shearing stress. The metal is very magnetic, but shows no polarity; sp. gr. at $17^\circ = 7.59$. A cut and polished surface has the appearance of iron, and when treated with acid is attacked uniformly. It dissolves completely in concentrated hydrochloric acid; nickel is absent, but platinum is present in small quantity, seemingly about 0.1 per cent. Platiniferous iron obtained by the simultaneous reduction of ferrous chloride and platinic chloride in a current of hydrogen is likewise completely soluble in hydrochloric acid.

The minerals associated with the native iron are quartz, mica, peridot, pyroxene, serpentine, triclinic feldspars, magnetite, and chromite. The platiniferous iron of Nichne-Tagilsk is also associated with peridotite rocks and with chromite, and the same is true of the nickeliferous iron from New Zealand and Piémont.

The compact character of this native iron indicates that it has not been reduced from the oxide by the action of reducing gases, and it seems most probable that it comes from infra-granitic depths where there is a deficiency of oxygen. C. H. B.

Formation of Natural Sulphides. By E. CHUARD (*Compt. rend.*, 113, 194—196).—Bronze implements found in lake mud containing organic matter are often covered with a thin layer of a pale-yellow colour, and with a metallic lustre. This layer is easily detached and is friable, yielding a greenish powder without metallic lustre. One speci-

men had the following composition : S, 27.09 ; Sn, 5.07 ; Fe, 31.05 ; Cu, 33.97 ; the remainder consisting of zinc and organic matter. It, therefore, agrees very closely with stanniferous copper pyrites, and is an example of a sulphide formed without the intervention of any mineral water. (Compare Daubrée, *Compt. rend.*, 80, 461.)

C. H. B.

Iron Pyrites containing Nickel and Cobalt. By E. W. NEUBERT and F. KOLLBECK (*Jahrb. f. Min.*, 1891, ii, Ref. 292—293 ; from *Jahrb. Berg. Hutt. Sachsen*, 1889, 106).—In the Himmelsfürst mine, at Freiberg, in Saxony, iron pyrites occurs in copper pyrites in the form of reddish-yellow grains, having a sp. gr. of 4.85 to 4.95. Analysis gave results in accordance with the formula $48\text{FeS}_2 + 7\text{NiS}_2 + 4\text{CoS}_2$.

B. H. B.

Eukairite, Umangite, and Luzonite from the Argentine. By F. KLOCKMANN (*Zeit. Kryst. Min.*, 19, 265—275).—In a collection of Argentine minerals presented to the School of Mines at Clausthal, the author has found three rare minerals of great interest.

1. *Eukairite*.—This rare mineral, which in Europe is known only at one Swedish locality, gave on analysis results in accord with the formula AgCuSe . The mineral occurs in the province of La Rioja in veins in limestone.

2. *Umangite*.—Associated with eukairite, there occurs a mineral, thought to be peacock-copper ore, which proved on analysis to be a variety of copper selenide. The analytical results obtained were as follows :—

Cu.	Ag.	Se.
56.03	0.49	41.44

The formula, therefore, is Cu_3Se_2 . Among all the known minerals there is no analogous compound of copper and selenium. The new mineral occurs in finely granular masses, with a hardness of 3.0 and a sp. gr. of 5.62. The lustre is metallic, and the colour cherry-red to violet.

3. *Luzonite*.—This mineral was discovered in 1874 by A. Weisbach. It exhibits the external characters of famatinite, and the chemical composition of enargite. Specimens of luzonite from a new locality, the Sierra de Famatina, gave on analysis results according well with those obtained by Winkler when analysing luzonite from Mancayan.

B. H. B.

Plumboferrite, a New Swedish Mineral. By L. J. IGELSTRÖM (*Zeit. Kryst. Min.*, 19, 167—170).—This mineral approaches most closely to franklinite and to Damour's jacobsite. In plumboferrite, however, the base is lead oxide instead of zinc oxide, as in franklinite, or manganous oxide, as in jacobsite. Plumboferrite occurs in the Jakobsberg manganese mine at Nordmarken, in veins in the granular limestone. On analysis, the mineral gave results corresponding with the formula $2\text{Fe}_3\text{O}_4 + \text{PbFe}_2\text{O}_4$.

B. H. B.

Mineralogical Notes. Antlerite. By W. F. HILLEBRAND (*Jahrb. f. Min.*, 1891, ii, Ref. 38—40 ; from *Bull. U.S. Geol. Surv.*, 55, 48—55).

—The bulletin contains a number of interesting analyses of minerals. Analyses are given of samarskite, of a zircon mineral, probably a mixture of cyrtolite, limonite, and a phosphate, and of white beryl.

A bright green mineral from the Antler mine, Arizona, gave on analysis—

CuO.	ZnO.	CaO.	SO ₃ .	H ₂ O.	Sp. gr.
68.19	0.29	0.05	20.46	11.11	3.93

This composition corresponds with the formula $3\text{CuSO}_4 + 7\text{Cu}(\text{OH})_2$. The author suggests for this mineral the name of *antlerite*, if on further investigation it should prove to be a new species.

B. H. B.

Barytes from Rumelange. By G. CESÀRO (*Jahrb. f. Min.*, 1891, ii, Ref. 7—8; from *Bull. Soc. géol. Belg.*, 14, 10).—In a large amonite from the oölitic iron ore of Luxemburg, crystals of barytes occur between crystals of calcite. The barytes crystals exhibit the following forms: 0P , ∞P , $\infty\bar{\text{P}}\infty$, $\infty\bar{\text{P}}2$, $\infty\bar{\text{P}}\infty$, $\infty\bar{\text{P}}3$, $\frac{1}{2}\bar{\text{P}}\infty$, $\frac{1}{4}\bar{\text{P}}\infty$, $\frac{1}{6}\bar{\text{P}}\infty$, $\bar{\text{P}}\infty$, P , $\frac{1}{2}\text{P}$. The face $\frac{1}{2}\bar{\text{P}}\infty$ has not hitherto been observed.

B. H. B.

Minerals from Tarapaca. By H. SCHULZE (*Jahrb. f. Min.*, 1891, ii, Ref. 21—22; from *Verh. deutsch. wissen. Vereins zu Santiago*, 2, 49—60).—In the alum deposits of the province of Tarapaca, the author has found soda alum in large quantities, pickeringite in fibrous masses, and bloedite and tamarugite, two minerals hitherto unknown in the district. On analysis, the minerals gave the following results:—

	SO ₃ .	Al ₂ O ₃ .	MgO.	CaO.	CuO.	CoO.	Cl.	Na ₂ O.	H ₂ O.	Total.
I.	48.07	—	12.12	—	—	trace	—	18.39	21.60	100.18
II.	45.66	14.48	—	0.20	trace	—	0.12	9.04	30.86	100.36
III.	37.28	11.85	4.64	0.31	0.01	0.01	0.02	—	46.10	100.22

I. Bloedite; formula $\text{Na}_2\text{SO}_4 \cdot \text{MgSO}_4 + 4\text{H}_2\text{O}$. II. Tamarugite; formula $\text{Na}_2\text{SO}_4 \cdot \text{Al}_2\text{S}_3\text{O}_{12} + 12\text{H}_2\text{O}$. For this new mineral the author suggests the name of tamarugite, from the Pampa del Tamaruga. III. Pickeringite; formula $\text{MgSO}_4 \cdot \text{Al}_2\text{S}_3\text{O}_{12} + 22\text{H}_2\text{O}$. B. H. B.

Place of Långbanite in the Mineral System. By H. BÄCKSTRÖM (*Zeit. Kryst. Min.*, 19, 276—283).—Four years ago G. Flink described a new mineral, which he termed länbganite. The mineral occurred in hexagonal crystals, and had the curious composition represented by the formula $37\text{Mn}_2\text{SiO}_4 + 10\text{Fe}_3\text{Sb}_2\text{O}_8$. It is not easily seen what place in the mineral system should be assigned to a mineral of so peculiar and complicated a composition. In order to throw further light on the question, the author has subjected this mineral to a fresh examination, with the following results:—

	Sb ₂ O ₃ .	SiO ₂ .	MnO.	FeO.	CaO.	MgO.	Total.
I.	13.96	9.58	65.44	3.10	1.73	0.53	94.34
II.	17.03	8.75	60.72	4.27	2.98	0.40	94.15
III.	15.41	10.88	66.29	10.32	—	—	102.90

For these analyses there were employed for I 0·7704 gram, and for II 0·7746 gram, the results being calculated so as to correspond with the analysis published by Flink (III). Correcting these analyses, under the assumption that manganese is present as Mn_2O_3 and MnO and antimony as Sb_2O_3 , the totals of the author's analyses amount to nearly 100 per cent. Långbanite may, therefore, be considered to be a mixture of compounds having the general formula $R_mR_nO_3$, in which $m + n = 6$. It is, however, not isomorphous with iron glance and titaniferous iron, but has an axial ratio of 1 : 0·8219, corresponding with that of the calcite series.

B. H. B.

Artificial Datholite. By A. DE GRAMONT (*Compt. rend.*, 113, 83—84).—A mixture of 25 grams of powdered borax and 5 grams of precipitated calcium silicate was heated in a platinum-lined steel pressure-tube at 400° for 36 hours. Besides other products, the melt yielded 1·5 grams of a crystalline powder, which had the composition and presented all the characters of natural datholite:—

		SiO ₂	CaO	H ₂ O	FeO	B ₂ O ₃	Density.
Artificial {	I ...	35·39	35·95	6·65	1·19	20·82	3·05
	II ...	—	35·96	6·37	—	—	—
Datholite from							
	Andreasberg ..	37·36	35·67	5·71	—	21·26	2·9
Botryolite from							
	Arendal	36·0	39·5	6·5	1·0	17·0	2·85

The iron was due to the impurity of the calcium silicate.

JN. W.

Rhyolites from Sweden. By N. O. HOLST (*Jahrb. f. Min.*, 1891, ii, Ref. 86—87).—On the Island of Ramsö, in the Lake of Mien, Sweden, a peculiar rock of volcanic character occurs, and this the author describes as rhyolite. Although the rock occurs in so limited an area, there are several distinct types. Descriptions and analyses of seven of these are given by the author. In the pumice-like variety, crystals of A. Schmidt's beaumontite are met with. An analysis of this mineral gave the following results:—

SiO ₂	Al ₂ O ₃	MgO	CaO	Na ₂ O	K ₂ O	H ₂ O	Total.
59·83	16·40	1·05	5·28	1·78	1·08	14·78	100·20

B. H. B.

Oligoclase and Biotite from Gailbach. By E. GOLLER (*Jahrb. f. Min.*, Beilage 6, 485).—The author gives analyses of oligoclase (I) and of biotite (II) from the diorite-gneiss of Gailbach. The results were as follows:—

	SiO ₂	TiO ₂	Al ₂ O ₃	Fe ₂ O ₃	FeO	CaO	MgO	K ₂ O	Na ₂ O	H ₂ O	Total.
I.	66·89	0·11	17·95	0·72	—	3·60	1·18	4·68	4·14	0·33	99·60
II.	37·98	1·82	18·20	1·19	12·16	3·45	13·93	5·95	1·44	2·61	98·73

The oligoclase thus has the composition Ab_3An_1 ; its sp. gr. is 2·665; that of the biotite is 3·072.

B. H. B.

Wernerite from Chili. By E. JANNETTAZ (*Jahrb. f. Min.*, 1891, ii, Ref. 28; from *Bull. soc. fran. de min.*, 12, 445—446).—Some specimens exhibited in Paris as tourmaline, consisting of long, fibrous prisms from the Llanca mine, Coquimbo, proved on examination to be dipyre (wernerite). Analysis gave the following results:—

SiO ₂ .	Al ₂ O ₃ .	Fe ₂ O ₃ .	CaO.	MgO.	Na ₂ O.	Ignition.	Total.
57·4	19·6	3·4	6·2	0·4	8·8	3·41	99·21

B. H. B.

Sigterite and Albite from Sigterö. By C. A. TENNE (*Jahrb. f. Min.*, 1891, ii, Mem. 206—210).—A year ago Rammelsberg published a note on a new variety of felspar, sigterite, from Sigterö, near Brevig. The interpretation of the analysis was based on the results of an optical examination which proved that the felspar resembled albite crystallographically, whilst the chemical analysis indicated a much more basic member of the felspar series. An examination of a second felspar, albite, occurring in association with sigterite, shows that the angles measured on the two minerals are identical. Further examination of the sigterite proves that it is a mixture of eläolite and albite, a conclusion with which Rammelsberg concurs.

B. H. B.

Natrolite of Montecatini. By E. MATTIROLO (*Zeit. Kryst. Min.*, 19, 203; from *Atti Accad. Sci. Torino*, 21).—The mineral discovered by Meneghini, in 1852, in the serpentine rocks of Tuscany was thought to be a new species differing from natrolite, inasmuch as it contained magnesia, and was therefore named *savite*. Sella pointed that out the mineral was crystallographically identical with natrolite. A careful analysis made by the author shows that magnesia and iron are entirely absent, and that the identity of *savite* and natrolite is unquestionable.

B. H. B.

Natrolite. By G. B. NEGRI (*Jahrb. f. Min.*, 1891, ii, Ref. 230; from *Rivista min. crist. ital.*, 7, 16—20).—Natrolite from the collection of the University of Padua, carefully selected and purified, gave on analysis the following results:—

	SiO ₂ .	Al ₂ O ₃ .	Na ₂ O.	K ₂ O.	H ₂ O.	Total.
I.	47·21	27·01	15·99	—	9·55	99·76
II.	46·97	27·12	15·95	0·40	9·42	99·86
III.	47·23	27·21	14·80	0·41	9·70	99·35
IV.	47·71	27·89	16·99	—	9·69	102·28

The mineral was derived from the following localities:—I, Salcedo; II, Montecchio Maggiore; III, Lugo; IV, Alta Villa. The analytical results are in accord with the formula $\text{Na}_2\text{Al}_2\text{Si}_2\text{O}_{10} + 2\text{H}_2\text{O}$.

B. H. B.

Amorphous Minerals from Budapest. By F. KOCH (*Zeit. Kryst. Min.*, 19, 198—199; from *Vegytemi lapok*, 5, 9—11).—The author gives analyses of two minerals obtained from the place, near Budapest, where the dolomite is in contact with the overlying marl.

At this contact the marl is converted into a reddish-brown, porous substance, on which a yellowish mineral (I) and a chalk-like, white substance (II) occur:—

	SiO ₂	Al ₂ O ₃	CaO.	MgO.	Fe ₂ O ₃	Ignition.	Total.
I. 40·48	30·06	2·92	0·33	trace	25·53	99·32	
II. 18·41	43·35	1·23	trace	trace	36·64	99·63	

The yellow mineral is thought by the author to be halloysite.

B. H. B.

Chloritoid from Champion, Michigan. By H. F. KELLER and A. C. LANE (*Zeit. Kryst. Min.*, 19, 383—385).—Since 1880, chloritoid has been known to occur in the upper peninsula of Michigan. The authors have, however, discovered it further west, at the Champion mine, in the form of dark-green, curved plates attaining a diameter of several centimetres, with a thickness in places of 4 mm. Its hardness is 6·5, and its sp. gr. 3·552. Analysis yielded the following results:—

SiO ₂	TiO ₂	Al ₂ O ₃	Fe ₂ O ₃	FeO.	MgO.	CaO.	K ₂ O.
24·29	0·28	34·00	10·55	20·52	1·29	0·59	0·97
		Na ₂ O.	H ₂ O.	Total.			
		0·35	6·75	99·59			

The formula deduced from these analytical results is

which differs from that of sismondine merely in the larger proportion of water present. The mineral occurs in an altered greywacke.

B. H. B.

Artificial Hornblende. By K. v. CHROUSTCHOFF (*Jahrb. f. Min.*, 1891, ii, Mem. 86—90).—Hornblende has not hitherto been prepared artificially. The author has, however, obtained successful results by employing a pear-shaped vessel of very thick glass, with a capacity of 25 c.c. A special furnace was erected for the reception of 12 of these vessels. They were filled with (1) a solution of colloïd silica containing 3 per cent. of silica, (2) an aqueous solution of alumina, (3) an aqueous solution of ferric hydroxide, (4) ferrous hydroxide, (5) lime water, (6) freshly prepared magnesium hydroxide suspended in water, and (7) a few drops of soda potash solution. Vessels filled with these ingredients were heated in the furnace for three months at 550°. At the end of the experiment, it was found that the interior of the vessel consisted of a greenish-brown mass containing hard grains, which, when washed out, proved to be distinct, dark, prismatic crystals exhibiting the crystallographical characters and possessing the chemical composition of hornblende. Besides hornblende, the other crystallised products formed were (1) pyroxene resembling diopside, (2) colourless, regular crystals, probably analcime, (3) very fine quartz crystals up to 2 mm. in length, and (4) thin tablets of orthoclase.

B. H. B.

The Basalt of the Stempel, near Marburg. By M. BAUER (*Jahrb. f. Min.*, 1891, ii, Mem. 156—205).—This is the first installment of an elaborate monograph on the basalt occurring at the hill known as the Stempel which rises above the sandstone of the Lahn plateau. The rock is best known on account of the zeolites, notably philipsite, which it contains. An analysis of the unaltered normal rock gave the following results:—

SiO ₂	TiO ₂	P ₂ O ₅	FeO	Al ₂ O ₃	MgO	CaO	K ₂ O	Na ₂ O	H ₂ O	Total
46.14	1.07	1.46	10.56	13.10	12.55	9.97	2.02	2.61	1.02	100.50

Of this rock and of the interesting minerals it contains, the author gives a detailed description based on microscopic observations.

B. H. B.

Basaltic Rocks of Hessen. By H. WOLFF (*Jahrb. f. Min.*, 1891, ii, Ref. 278—280; from *Sitzungsber. phys. med. Soc. Erlangen*, 22, 118—140).—In connection with the geological survey of Niederaula, and Neunkirchen by the officers of the Prussian Government, the author has made a careful chemical examination of the basaltic rocks which have been collected during the progress of the work. He gives four analyses of felspar-basalts, seven analyses of basanites, and two analyses of nepheline-basalt. In appearance these rocks differ but slightly, the differences being solely in chemical composition.

B. H. B.

Rocks and Minerals from Corsica. By G. RUPPRECHT (*Jahrb. f. Min.*, 1891, ii, Ref. 289—291).—The author gives analyses of (1) granite from Ajaccio, (2) grey quartz-porphyr from Ajaccio, (3) finely-granular, red muscovite-granite from Apiello, (4) large, pink felspars (orthoclase) from the granitite of Solaro, of Apiello, and of the Couvent de la Trinité, (5) albite from the same rocks, (6) black mica from the Couvent de la Trinité rock, (7) hornblende, and (8) felspar from the diorite from the Valle d'Orezza.

B. H. B.

Chalybeate Waters containing Free Sulphuric Acid. By E. WILLM (*Compt. rend.*, 113, 87—89).—The mineral waters of Rennes-les-Bains (Aude), which contain ferrous, aluminium, calcium, magnesium, and sodium sulphates, and sodium chloride, have a powerfully acid reaction, due to the presence of from 1.17 to 17.01 parts per 100,000 of free sulphuric acid. Surface efflorescences, consisting of ferric and aluminium sulphates with siliceous matter, have been observed in an old jet quarry in the neighbourhood of the well yielding the largest proportion of acid.

JN. W.

Organic Chemistry.

Mechanical Determination of the Arrangement of the Carbon Atoms in Organic Compounds. By G. HINRICHS (*Compt. rend.*, 113, 313—315).—In the structural formulæ for the normal paraffins, the carbon atoms are shown as forming a straight line. All those properties which depend solely on structure should be continuous functions of the number of carbon atoms in the molecule, whether the number of carbon atoms is even or uneven. The melting points of the paraffinoid hydrocarbons containing an uneven number of carbon atoms are less, however, than they should be according to the above rule. If the melting point is a function of the moment of inertia of the molecule for its natural axis of rotation, the author shows that the above fact would lead to the arrangement of the carbon atoms in a zig-zag line. H. C.

Action of Boron Fluoride on Nitriles. By G. PATEIN (*Compt. rend.*, 113, 85—87).—Boron fluoride combines in molecular proportions with aliphatic and aromatic nitriles. When a rapid current of the fluoride is passed into acetonitrile, it is absorbed with evolution of heat, and, on cooling, colourless, deliquescent, fuming crystals, having the composition MeCN, BF_3 , separate. The substance melts at 120° , sublimes, and may be preserved in sealed tubes containing boron fluoride. It is soluble in alcohol and ether, and with decomposition in water and alkalis. Similar compounds are formed with benzonitrile and toluonitrile. Hydrogen cyanide forms a similar very unstable compound with absorption of heat. JN. W.

Action of Ammonia on some Compounds of the Haloid Salts of Mercury. By R. VABET (*Compt. rend.*, 112, 1312—1314).—When a solution of mercury cadmium iodo-cyanide,

is allowed to drop into aqueous ammonia until a permanent precipitate is formed, and the precipitate is allowed to remain in contact with the mother liquor for some time with occasional agitation, a yellowish, amorphous powder is obtained, which must be dried rapidly on filter paper. It is mixture of ammonio-cadmium iodide with the compound $\text{HgCy}_2, \text{CdCy}_2, \text{HgI}_2, 4\text{NH}_3$ or its isomeride $2\text{HgCy}_2, \text{CdI}_2, 4\text{NH}_3$, the ammonia having produced a reaction the inverse of that which gave rise to the original salt, and again formed cadmium iodide. Similar results are obtained by dissolving mercury cadmium iodo-cyanide in ammonia.

Mercury potassium iodo-cyanide dissolves abundantly in aqueous ammonia at 40° , and separates unchanged on cooling.

Ammonia acts slowly on mercuric cyanide, but if the moist salt is heated in a current of the gas at 100° until quite dry and the passage of the gas is afterwards continued for some time at the ordinary temperature, the compound $\text{HgCy}_2, 2\text{NH}_3$ is obtained as a white,

amorphous powder, which alters readily when exposed to air, losing ammonia rapidly and absorbing water.

Mercury barium chlorocyanide, under similar conditions, yields the compound $2\text{HgCy}_2, \text{BaCl}_2, 4\text{NH}_3$, which alters rapidly on exposure to air, is only slightly soluble in ammonia, and is decomposed by water. The chlorocyanide absorbs ammonia much more rapidly than either of its constituent salts separately, and the compound seems to be more stable than the compound formed by either of the simple salts. C. H. B.

The Cyanogen Compounds of Magnesium. By R. VARET (*Compt. rend.*, 112, 1449—1451).—A triple salt of the composition $\text{MgCy}_2, \text{HgCy}_2, \text{HgI}_2 + 8\text{H}_2\text{O}$ is formed when small quantities of magnesium iodide are thrown into a concentrated solution of mercuric cyanide maintained at $60\text{--}70^\circ$, using 15 grams of magnesium iodide to 25 grams of mercuric cyanide. The filtered liquid carefully evaporated on the water-bath deposits, on cooling, large, light-yellow, transparent lamellæ, which may be dried in paper. When the salt is carefully heated, it first yields hydrocyanic acid, water, and mercuric iodide, and subsequently, on fusion, an abundant sublimate of mercuric iodide and mercury, together with cyanogen. From the character of this decomposition, it is evident that the compound is more complex than would be formed by a simple union of mercuric cyanide and magnesium iodide. When a solution of the iodocyanide is boiled with ammonium picrate, the fine-red coloration of ammonium isopurpurate is produced; such a reaction does not occur with mercuric cyanide. Similarly, copper sulphate yields a precipitate of mercuric iodide and cupric cyanide, the latter further decomposing into cuprous cyanide and cyanogen. Mercuric cyanide does not react with the oxygen salts of copper.

If a concentrated solution of magnesium bromide be dropped slowly into a saturated solution of mercuric cyanide at 50° , and the mixture evaporated, white, nacreous, silky lamellæ of the formula $\text{MgCy}_2, \text{HgCy}_2, \text{HgBr}_2 + 8\text{H}_2\text{O}$ are deposited. This substance is very hygroscopic and soluble in water, and is unstable in air. Its constitution is not clearly established. W. T.

Fulminates. By H. N. WARREN (*Chem. News*, 64, 28).—Copper fulminate, obtained by digesting a solution of silver fulminate with copper filings, when reduced by electrolysis, yielded copper, hydrocyanic acid, and ammonia in abundance, also ammonium fulminate and fulminic acid. Cuprammonium fulminate, obtained by treating copper fulminate with excess of ammonia, dried over sulphuric acid, and decomposed by hydrogen sulphide, yielded copper sulphide, carbamide, and ammonium thiocyanate. Silver fulminate, by the action of dry silicon fluoride, yielded silver fluoride and an explosive gas. By the action of chlorine, bromine, or iodine, the haloid silver salt and chloro-, bromo-, or iodo-picrin were obtained. D. A. L.

Allyl Alcohol and its Formation from Dichlorhydrin and Sodium. By H. TORNÖE (*Ber.*, 24, 2670—2678).—Aqueous allyl

alcohol, which has been kept over freshly ignited potassium carbonate, still contains a considerable quantity of water; on repeated fractional distillation, such a mixture can be separated into two portions, boiling constantly at about 87.5° and 97° respectively. The fraction of lower boiling point seems to be a mixture of 72.3 per cent. of allyl alcohol and 27.7 per cent. of water; the fraction of higher boiling point is almost anhydrous allyl alcohol, but contains a small quantity of acraldehyde. On treating the almost anhydrous allyl alcohol with dry chlorine, a large quantity of acraldehyde is formed, and the yield of pure dichlorhydrin (b. p. $181-186^{\circ}$, with slight decomposition) is only about 20 per cent. of the theoretical.

Both the dichlorhydrins are very stable towards acid reducing agents, and are not acted on by nascent hydrogen or by stannous chloride; when heated with hydriodic acid and amorphous phosphorus, they both yield isopropyl iodide, and a small quantity of a liquid boiling at about $34-36^{\circ}$, which is most probably isopropyl chloride.

It has been previously shown by Hübner and Müller (*Annalen*, 159, 168) that allyl alcohol is produced by the action of sodium on an anhydrous ethereal solution of dichlorhydrin (b. p. 144°); the author succeeded in isolating impure epichlorhydrin from the products of this reaction and proved its presence by converting it into dichlorhydrin.

When an anhydrous ethereal solution of epichlorhydrin is treated with sodium, only a trace of a liquid, which seems to be impure allyl alcohol, is obtained, so that it is impossible to assume that the production of allyl alcohol from dichlorhydrin, in the reaction just referred to, is due to the intermediate formation of epichlorhydrin.

The two acetylchlorhydrins are converted into one and the same allyl acetate on treatment with sodium in anhydrous ethereal solution.

F. S. K.

Rotatory Power of Compounds of Mannitol with Acid Molybdates. By D. GERNEZ (*Compt. rend.*, 112, 1360—1363).—The author has previously shown (*Abstr.*, 1890, 744) that compounds such as active malic acid having both acid and alcoholic functions in aqueous solution form compounds with optically inert substances such as the molybdates, which compounds have a greater rotatory power than the original acid. The present paper describes similar compounds formed by the alcohol mannitol. Solutions were employed containing 0.7583 gram and 1.5866 grams of mannitol, to which were added varying quantities of the acid sodium or ammonium molybdates respectively, differing by 1/12 equivalent, and sufficient water to make the total volume 24 c.c. The initial negative rotation of the mannitol is changed to a positive rotation on the addition of the first 1/12 equivalent of acid molybdate; this rotation increases regularly on the addition of further quantities of the acid salt until maxima of $2^{\circ} 45'$ and $5^{\circ} 16'$ respectively are attained with 6.75/12 equivalent of the acid molybdate. This proportion of the acid salt corresponds with 3.9875 equivalents of molybdic acid to 1 equivalent of mannitol. The rotation observed is slightly less if the ratio be 4 to 1. As normal sodium molybdate has no action on mannitol, there is, considering only the molybdic acid not saturated by the soda, 2.25 equivalents of

molybdic acid to 1 equivalent of mannitol, or 9 to 4 respectively as the proportions in the compound formed. Further additions of the salt give gradually decreasing rotations, indicating the decomposition of the compound corresponding with the maximum and a tendency towards some other state of equilibrium. W. T.

Configuration of Grape Sugar and its Isomerides. By E. FISCHER (*Ber.*, 24, 2683—2687).—In the last paper on this subject (this vol., p. 1173), the configuration of grape sugar was expressed by the formula

as, however, in the case of such complicated molecules, the employment of the signs + and - for denoting the arrangement in space may easily give rise to mistaken views, it becomes necessary to give a more complete explanation of the formulæ. For this purpose, the four asymmetric carbon atoms in the molecule of grape sugar may be numbered as shown below :—

Van't Hoff, in his general considerations, on which the author's special deductions are based, only compares the carbon atom 1 with the carbon atom 4, and 2 with 3; consequently, in the case of grape sugar, the arrangement of the hydrogen atom and the hydroxyl group around 1 is the reverse of that around 4, whilst the arrangement around 2 and 3 is the same. The arrangement of the asymmetric group around the carbon atom 1 can, however, be also compared with that of the two central asymmetric groups, as was done by the author in fixing the relationship of grape sugar to xylose and arabinose; it was then shown that the arrangement of the hydrogen atom and hydroxyl group around the carbon atom 1 is identical with that around 3. From a superficial examination, it might be concluded that this is also so in the case of the carbon atoms 1 and 2, but as a matter of fact the reverse is true.

With the aid of models, it is easily seen that, in the case of the carbon atom 2, the sign varies according as it is compared with 1 or 3. As, therefore, the above method of expressing the configuration of grape sugar is ambiguous, it is advisable to do so in another way.

In the first place, the molecules of dextro-, levo-, and inactive tartaric acids can be constructed (with the aid of Friedländer's india-rubber models), and laid on paper in such a way that the four carbon atoms are arranged in a straight line, the hydrogen atoms and hydroxyl groups standing above the plane of the paper; the projections of these models would then be the following :—

On proceeding in a similar manner with the models of d.- and l.-saccharic acids, the two following projections are obtained:—

As it is immaterial which of these two configurations is assigned to d.-saccharic acid, it may be assumed to have that represented by the formula I; the configurations of grape sugar and its isomerides would then be expressed as follows:—

The configurations of the two inactive dicarboxylic acids of the dulcitol series, which are probably represented by mucic acid and allomucic acid, may be denoted by the following formulæ:—

This manner of expressing configuration can also be adopted in the case of the pentoses; its use is even more advantageous in the case of the more complex molecules of the heptoses, octoses, &c., where the ambiguity of the signs + and - constantly becomes greater. The configurations of the two pentoses, for example, and of the tri-hydroxyglutaric acids obtained therefrom, may be represented by the following projections:—

Arabinose.

Xylose.

Active acid from
arabinose.Inactive acid from
xylose.

The advantage of the new formulæ is more particularly noticeable in considering those reactions in which an increase or decrease in the number of asymmetric carbon atoms takes place; as, for example, in the oxidation of levulose to inactive tartaric acid; this change is very simply expressed in the following way:—

d -Fructose.

Inactive tartaric acid.

F. S. K.

Stachyose. By A. v. PLANTA and E. SCHULZE (*Ber.*, 24, 2705—2709).—Stachyose (*Abstr.*, 1890, 1088), like raffinose, is a triose, and on inversion it yields galactose, grape sugar, and levulose; mannose and pentoses could not be detected in the solution of the inverted sugar. Since stachyose yields 37—38 per cent. of mucic acid on oxidation with nitric acid, it may be assumed that the molecule of this sugar is formed by the combination of 3 mols. of galactose either with 2 mols. of grape sugar and 1 mol. of levulose, or with 1 mol. of grape sugar and 2 mols. of levulose; it is probable, therefore, that stachyose has the molecular formula $\text{C}_{38}\text{H}_{64}\text{O}_{28}$. F. S. K.

Lupeol. By A. LIKIERNIK (*Ber.*, 24, 2709—2710).—Lupeol (this vol., p. 551) may be considered as a homologue of α - and β -amyrin (compare Vesterberg, this vol., p. 165). The relationship of lupeol to the amyryns is shown by the fact that they all give substitution, and not additive, products with bromine; a chloroform solution of each of the three compounds turns reddish-violet on the addition of acetic anhydride and a little concentrated sulphuric acid. F. S. K.

Conversion of Starch into Dextrin by the Butyric Ferment. By A. VILLIERS (*Compt. rend.*, 113, 144—145).—When starch paste is inoculated with the butyric ferment and kept at 40°, the rotatory power at first increases, reaches a maximum after 2½ days, and then slowly decreases, the starch almost entirely disappearing. When filtered through biscuit porcelain, and kept at 40° for several days, the rotatory power of the solutions undergoes no further change. They give no starch reaction with iodine. If a small quantity of starch is added to the sterilised solutions, and they are then kept at

40°, the starch disappears after some days, but the rotatory power of the liquid remains practically unchanged.

In the conversion of starch into dextrin by the action of the butyric ferment, the latter secretes a soluble product capable of producing the conversion in the absence of any organisms. This product is formed continually in very small quantities, and its activity seems to be exhausted almost as fast as it is formed.

C. H. B.

Bleaching of Cotton by Hydrogen Peroxide. By PRUD'HOMME (*Compt. rend.*, 112, 1374—1376).—The superiority of the results obtained in bleaching cotton when calcined magnesia is added to the hydrogen peroxide used is due to the formation of magnesium peroxide, which is more stable than hydrogen peroxide at 100°. 6 per cent. hydrogen peroxide, diluted with 10 parts water and boiled for half an hour, has its titration value reduced to one-tenth of that shown before boiling. If calcined magnesia, to the amount of 5 per cent. of the weight of hydrogen peroxide, be added, the titration value is only reduced to nine-tenths. Magnesia is subjected to the action of 3 per cent. hydrogen peroxide for some time at the ordinary temperature, filtered, washed, and dried at 100—105°; the active oxygen, titrated with permanganate, corresponds with the formula $3\text{Mg}(\text{OH})_2 + \text{MgO}(\text{OH})_2$ for the dry product. This substance has an alkaline reaction, and loses all its active oxygen at about 300°. Magnesium peroxide is also formed when the metal is dissolved in hydrogen peroxide.

Zinc and cadmium also form peroxides; that of zinc has probably the formula $2\text{ZnO} + \text{ZnO}(\text{OH})_2$.

Hydrogen peroxide has a direct action not only on the various colouring matters present, but even on such substances as cellulose. Fatty substances give off much carbonic anhydride on boiling with hydrogen peroxide, due to the oxidation of the glycerol set free by the saponification brought about by the magnesia employed in the process. Slightly acid hydrogen peroxide attacks neutral fats on boiling, liberating fatty acids and disengaging carbonic anhydride. Under the joint action of magnesia and hydrogen peroxide, the fatty acids are oxidised with production of carbonic anhydride. Oleic acid is, under these conditions, partially transformed into palmitic acid, just as when treated with caustic potash.

In bleaching by hydrogen peroxide, cellulose is converted into oxycellulose, recognised by dyeing with basic colouring matters which fix on oxycellulose without a mordant. The alteration of cellulose is greater if impregnated with concentrated caustic soda before treating it with hydrogen peroxide.

This action of hydrogen peroxide is greatly augmented by the presence of metallic oxides, which appear to serve as vehicles for the active oxygen; the bleaching, therefore, should be preceded by treatment with a very dilute acid. A piece of cloth mordanted with iron, chromium, and aluminium, and boiled for one or two hours with magnesia and hydrogen peroxide, is strongly attacked in the mordanted portions. The action of hydrogen peroxide on cellulose

presents great analogies with that of cuprammonium solutions, which also act as oxidising agents, forming oxycellulose.

Cotton cloth treated with caustic soda at 36° and thoroughly washed is acted on more strongly by cuprammonium solutions of moderate concentration than cloth not so treated. It is concluded that, contrary to the received opinion, cellulose is attacked and suffers transformation under the action of Schweitzer's reagent.

W. T.

Ureides from Normal Acids. By C. MATIGNON (*Compt. rend.*, 112, 1367—1369).—The heats of combustion of formylcarbamide and acetylcarbamide are respectively +207·3 Cal. and +360·9 Cal.; the corresponding heats of formation are +119·3 Cal. and +129 Cal.

In accordance with the difference, 153·6 Cal., between the heats of combustion of these two successive homologues, there is great similarity in their reactions with the same reagents. Formic and acetic acids differ considerably in properties, and the difference between the heats of combustion of these acids taken in the solid state is only 140 Cal.

Formic acid and urea in solution combine with liberation of +13·4 Cal., whereas acetylcarbamide is not formed from acetic acid and urea in solution, as the reaction would require an absorption of 0·2 Cal. The synthesis of acetylcarbamide from acetamide and urea has not been accomplished; it would require an absorption of 12·5 Cal. Acetylcarbamide and formylcarbamide yield flocculent precipitates with mercuric chloride and potash. The formula of the compound with formylcarbamide is probably $\text{COH}\cdot\text{N} < \begin{smallmatrix} \text{CO} \\ \text{Hg} \end{smallmatrix} > \text{NH}$.

Urea acetate, $\text{CON}_2\text{H}_4\cdot\text{C}_2\text{H}_3\text{O}_2 + 2\text{H}_2\text{O}$, forms large, deliquescent crystals; the heat of solution at 16° is -8·8 Cal. at a concentration of $\frac{1}{8}$ mol. per litre. Its heat of formation is +31 Cal.; the smallness of this number accounts for the easy dissociation of the salt by water.

W. T.

Products of Oxidation of Uric Acid. By C. MATIGNON (*Compt. rend.*, 112, 1263—1266).—*Allantoin*.—Heat of combustion at constant pressure, +413·8 Cal.; heat of formation, +170·4 Cal.; heat of dissolution at 15°, -7·5 Cal.

Alloxan.—Heat of combustion, +278·5 Cal.; heat of formation, +236·7 Cal.; heat of dissolution, +4·1 Cal., -4·2 Cal., and -9·0 Cal. in the three states of hydration respectively.

Alloxantin.—Heat of combustion, +586·3 Cal.; heat of formation, +513·1 Cal.; heat of dissolution at 15°, -9 Cal.

$\text{C}_4\text{O}_6\text{N}_2\text{H}_2 \text{ sol.} + \text{H}_2\text{O sol.} = \text{C}_4\text{O}_6\text{N}_2\text{H}_4 \text{ develops } +9\cdot0 \text{ Cal.}$

$\text{C}_4\text{O}_6\text{N}_2\text{H}_4 \text{ sol.} + 3\text{H}_2\text{O sol.} =$

$\text{C}_4\text{O}_6\text{N}_2\text{H}_4\cdot 3\text{H}_2\text{O sol.} \dots\dots\dots \text{,,} \quad +6\cdot9 \text{ Cal. } (3 \times 2\cdot3).$

It follows that the entrance of the first molecule of water into the molecule of alloxan causes a development of heat almost as great as the heat of hydration of phosphoric anhydride, and this result confirms

Baeyer's view, that the compound $C_4O_4N_2H_2$ is the anhydride of alloxan.

It would seem, therefore, that the oxidation of uric acid should always produce allantoin, and this is true so long as no secondary reaction takes place with the same velocity as the principal reaction; for example, when potassium permanganate is the oxidising agent. If, on the other hand, nitric acid is the oxidising agent, nitrous acid is formed, and this at once attacks the urea, and the heat developed by this simultaneous secondary reaction is sufficient to turn the balance in favour of alloxan. The thermochemical results explain the well-known fact that the action of oxidising agents on uric acid yields either allantoin or alloxan, but never both at the same time.

C. H. B.

Parabanic and Oxaluric Acids. By C. MATIGNON (*Compt. rend.*, 113, 198—200).—*Parabanic Acid*.—Heat of combustion, +212·7 Cal.; heat of formation, +139·2 Cal.; heat of dissolution at 20°, -5·1 Cal.

Oxaluric Acid.—Heat of combustion, +211 Cal.; heat of formation, +209·9 Cal.

The formation of parabanic acid from oxalic acid and urea would develop +2·2 Cal., and the formation of oxaluric acid would develop +2·5 Cal. These numbers are very low, and explain the difficulty of passing directly from urea to the ureides. The conversion of parabanic acid into oxaluric acid by elimination of water would develop only +0·3 Cal.

A cold solution of potassium hydroxide, containing 1 gram-molecule in 20 litres, rapidly converts both parabanic acid and oxaluric acid into normal potassium oxalate, the change in the case of parabanic acid being accompanied by the development of +24·4 Cal., the acid being solid and the potash and the products dissolved. The heat of formation deduced from this result is 138·7 Cal., whilst the direct determination gives 139·2 Cal.

Potassium oxalurate, prepared by dissolving oxaluric acid in an equivalent quantity of potash solution and evaporating the liquid, is different from the oxalurates described by Menschutkin and Strecker respectively. It crystallises in stellate groups of slender, anhydrous, prismatic needles.

The action of the first equivalent of potash on oxalic acid develops +34·2 Cal.

C. H. B.

Action of Diazobenzene Chloride on Acetone. By E. BAMBERGER and P. WULZ (*Ber.*, 24, 2793—2797).—A study of the properties of a hydronaphthol obtained from tetrahydronaphthylene oxide

(this vol., p. 1073) led Bamberger to the conclusion that compounds containing the radicle $\text{CH}_2\cdot\text{CO}$ (or $\text{CH}\cdot\text{CH}\cdot\text{OH}$), whether belonging to the fatty or the aromatic series, must be capable of forming colouring matters on treatment with diazotised bases in the presence of alkalis. This opinion has been verified with acetone, acetaldehyde, propaldehyde, cinnamaldehyde, acetophenone, camphor, &c, all of which give intense, dark claret coloured solutions. Formaldehyde, which does not contain the radicle, does not give the reaction, but, on the other hand, substances like lactic acid and dextrose, and, in particular, ethylenic compounds, such as allyl alcohol, dihydronaphthalene, dihydrobenzaldehyde, &c., form colouring matters under the conditions named.

When a mixture of acetone (12 grams) with a solution of diazobenzene chloride (prepared from 18.6 grams aniline) is slowly stirred into carefully cooled 20 per cent. aqueous soda (200 grams), a red coloration is produced, and the mixture becomes turbid, finally depositing a brownish-black resin. The product can be obtained in a crystalline form by dissolving it in well-cooled sulphuric acid, and, after 12 hours, pouring the deep blue solution on to ice, drying the reddish-brown, flocculent precipitate, and then carefully extracting with ether. On evaporating the deep red ethereal solution, a crystalline residue is obtained which can be purified by repeated crystallisation from alcohol. The compound has the composition $\text{C}_{15}\text{H}_{14}\text{N}_2\text{O}$, and is more probably a bis-hydrazone of mesoxalaldehyde than a disazo-derivative of acetone. It crystallises either in lustrous, garnet-red prisms, showing an intense, steel-blue, metallic shimmer, or by rapid crystallisation in tufts of flat needles, melts at $134-135^\circ$, and dissolves easily in the ordinary organic solvents, but only very sparingly in water. It has feebly basic properties, and dissolves in concentrated mineral acids, forming deep violet-blue solutions, from which the colouring matter is precipitated unchanged on the addition of water. The compound is destitute of tinctorial power, but its sulphonic acid, contained in the aqueous solution after extraction with ether, dyes wool and silk a bright chestnut-brown in an acid bath.

In the concluding portion of the paper, the authors draw attention to the difference between this reaction and that employed by Penzoldt and Fischer for the detection of aldehydes (Abstr., 1883, 829).

W. P. W.

Ethereal Nitrosocyanacetates. By P. T. MULLER (*Compt. rend.*, 112, 1372-1373).—These salts are prepared by the action of amyl nitrite on the sodium derivatives of ethereal cyanacetates, with subsequent treatment of the sodium salts produced with sulphuric acid.

Ethyl Nitrosocyanacetate.—An equivalent quantity of sodium dissolved in absolute alcohol is added, little by little, to ethyl cyanacetate (1 mol.), and amyl nitrite (1 mol.) is added, in small portions at a time, to the resulting mass, which is then heated to $50-60^\circ$. It is cooled, washed with ether, and precipitated with dilute sulphuric acid. The oil is dissolved in ether, dried, and crystallised by evaporation. Ethyl nitrosocyanacetate, $\text{NO}\cdot\text{CH}(\text{CN})\cdot\text{COOEt}$, forms small, white

crystals, melts at 127—128°, and is very soluble in water, alcohol, and ether, less so in benzene. The sodium salt crystallises in small, yellow, fibrous prisms containing 5 mols. H_2O . It is formed directly by the action of amyl nitrite on ethyl sodiocyanacetate; the product is evaporated to dryness and dissolved in alcohol; the salt is precipitated by the addition of benzene.

Methyl nitrosocyanacetate is obtained, by the same method as its homologue, in the form of small, tabular crystals melting at 119°. The sodium salt occurs in yellow, flat prisms containing $1\frac{1}{2}$ mols. H_2O .
W. T.

Cyanostearic Acid, Hexadecylmalonamic Acid, and Hexadecylmalonic Acid. By C. HELL and J. SADOWSKY (*Ber.*, 24, 2778—2785).— *α -Cyanostearic acid*, $CN \cdot C_{17}H_{34} \cdot COOH$, is prepared by dissolving ethyl α -bromostearate (this vol., p. 1336) (50 grams) in alcohol, adding potassium cyanide (14 grams) dissolved in the smallest quantity of hot water, and heating the mixture in a reflux apparatus for 5—6 days, then collecting the dark precipitate, washing with alcohol, dissolving in water, adding sulphuric acid, filtering from the humus substance which separates, extracting with ether, and finally purifying the acid by crystallisation from glacial acetic acid, and subsequently from a mixture of alcohol and light petroleum; it forms small, iridescent, transparent plates or prisms, melts at 83·5°, and is readily soluble in alcohol, ether, and glacial acetic acid, but almost insoluble in light petroleum. When the acid is heated at 200—250°, carbonic anhydride is evolved and stearonitrile (Krafft and Stauffer, *Abstr.*, 1882, 1274) is formed.

Hexadecylmalonamic acid, $CONH_2 \cdot C_{17}H_{34} \cdot COOH$, is obtained by boiling α -cyanostearic acid with alcoholic potash for 2—3 days, distilling off the alcohol, dissolving the residue in water, precipitating with hydrochloric acid, redissolving in ether, and crystallising the plates which first separate from the ethereal solution from a mixture of light petroleum and a little alcohol. The acid forms delicate, silky scales, and is readily soluble in hot alcohol, ether, and hot benzene, but only sparingly in light petroleum; it begins to decompose below its melting point into stearamide (m. p. 108°), and when heated at 130—150°, it is completely converted into the latter.

Hexadecylmalonic acid, $C_{17}H_{34}(COOH)_2$, is formed by boiling hexadecylmalonamic acid with alcoholic potash for 3—4 days, or α -cyanostearic acid with an excess of the latter for 6—7 days, isolating in the same manner as hexadecylmalonamic acid, and finally crystallising from glacial acetic acid; it crystallises in lustrous, pointed, rhombic tablets, melts at 121·5—122°, and is readily soluble in alcoholic ether, hot benzene, or glacial acetic acid, but almost insoluble in light petroleum, and quite so in water. The acid is identical with the cetylmalonic acid described by Guthzeit (*Abstr.*, 1881, 408). When heated at 160—180°, hexadecylmalonic acid is converted into stearic acid with the evolution of carbonic anhydride. The salts likewise decompose on heating, as follows: the *barium salt* at 270—290°, the *cadmium salt* at 250°, the *zinc salt* at 230°, the *copper salt* at 210°, and the *silver salt* at 190°.
A. R. L.

Acids from Baku Petroleum. By O. ASCHAN (*Ber.*, 24, 2710—2724; compare Abstr., 1890, 737).—Heptanaphthenecarboxylic acid, $C_{15}H_{14}O_2$, has been previously isolated by Markovnikoff; it boils at 237—239°, and is with difficulty rendered anhydrous. The coefficient of refraction for sodium light is $N = 1.4486$, and the molecular refractive power = 38.7, which agrees with the theory. The acid is unaffected by bromine or potassium permanganate. The *methyl salt* boils at 190—192°; the specific gravity = 0.9357, 18°/18°. The *potassium* and *sodium salts* are crystalline and readily soluble in water or alcohol. The *calcium salt*, $(C_7H_{13}COO)_2Ca$, crystallises from water in long needles, and is deposited in an amorphous condition on heating a cold, saturated solution. The *barium salt* is obtained in anhydrous, lustrous plates; the *silver salt* is amorphous. All these compounds resemble the corresponding hexanaphthenecarboxylates in general properties. The *chloride*, $C_7H_{13}COCl$, is a strongly refractive, dense liquid, which boils at 193—195° and gradually undergoes decomposition. The *amide*, $C_7H_{13}CONH_2$, is most readily prepared by heating the acid (5 parts) with ammonium thiocyanate (4 parts) until a portion becomes crystalline on cooling; it is deposited from a mixture of ether and light petroleum in silvery, lustrous plates; it melts at 133°, but sublimes below 100°, and boils at about 250° with slight decomposition. The compound is somewhat volatile with steam, and combines with hydrochloric acid and calcium chloride. The *nitrile*, $C_7H_{13}CN$, is formed by the distillation of the preceding compound; it boils at 199—201° (corr.) and has a characteristic smell; the coefficient of refraction is $[n]_D = 1.4452$.

Heptanaphthenamine, $C_7H_{15}NH_2$, is readily prepared from the amide by Hofmann's method; the yield is 66 per cent. of theory. It boils at 151—153° (corr.), and is a colourless liquid, absorbing carbonic anhydride from the atmosphere, and giving the ordinary reactions for primary amines. The *hydrochloride* forms large, lustrous plates, which are excessively soluble in water or alcohol, and are very hygroscopic; the *platinochloride* crystallises in large, lustrous, golden, hexagonal plates. Attempts to prepare heptanaphthene alcohol by means of the diazo-reaction were not very successful; a liquid was obtained which boiled at 161—163°: it was, however, coloured, and contained nitrogen.

Heptanaphthenecarboxylic acid is oxidised on boiling with 10 parts of nitric acid (sp. gr. 1.3); acetic acid, carbonic anhydride, and oxalic acid are formed, together with a viscid, uncrystallisable liquid, which is readily soluble in water and which appears to be a polybasic hydroxy-acid; the *silver salt* contains, as the mean of several analyses, 61.12 per cent. of silver. By the prolonged action of phosphorus and hydriodic acid on heptanaphthenecarboxylic acid at 200—240°, a hydrocarbon is obtained which boils at 117—118° and is identical with the octonaphthene, C_8H_{16} , isolated by Markovnikoff from Caucasian petroleum. The yield is 29 per cent. It thus appears that the naphthene acids are simply monocarboxylic acids of the naphthenes. This portion of the paper concludes with some polemical remarks on a recent communication of R. Zložiecki, respecting the constitution of petroleum acids (compare this vol., p. 999).

Octonaphthenecarboxylic acid, $C_{28}H_{46}O_2$, has been previously described by Markovnikoff; it boils at $251-253^\circ$ (corr.), and has a sp. gr. = 0.9893 , $0^\circ/0^\circ$; its coefficient of refraction is $[n] = 1.453$, and the molecular refractive power = 43.0 . The *methyl salt* boils at $211-213^\circ$ and is very hygroscopic. The *barium* and *calcium salts* are not decomposed by carbonic anhydride; the former is crystalline and sparingly soluble in cold water, but readily dissolves in alcohol. The *chloride* is a dense, oily liquid, which boils at $206-208^\circ$ and slowly decomposes in presence of water. The amide crystallises from a mixture of benzene and light petroleum in large, thin, lustrous plates, and melts at $128-129^\circ$.
J. B. T.

Propylideneacetic Acid. By P. OTT (*Ber.*, 24, 2600—2604).—Propylideneacetic acid is obtained by warming equal weights of malonic acid and propaldehyde with half the weight of acetic acid on the water-bath as long as carbonic anhydride is evolved. The reaction usually takes from 3 to 4 days. The mixture is then fractionally distilled; the fractions boiling at $180-200^\circ$ and $200-220^\circ$ contain the greater part of the product. From former experiments, the product is known to be a mixture (this vol., p. 821); it was worked up as follows:—The fraction boiling at $180-200^\circ$ is neutralised with barium carbonate, evaporated to dryness, and extracted with absolute alcohol until quite white. It is then dissolved in water, the solution evaporated until a crust separates, which dissolves on cooling, and to the clear cold solution alcohol is added until a considerable portion of the salt is precipitated. The precipitate is then dissolved by heating the mixture, and, on cooling, the barium salt separates in large, nacreous leaves. *Barium propylideneacetate* crystallises without water, is very characteristic, is insoluble in absolute alcohol, easily soluble in water, and more so in cold than in hot water. Pure propylideneacetic acid is obtained by decomposing the above salt with hydrochloric acid, and extracting with ether. It has an odour somewhat like that of crotonic acid, is quite colourless, boils at 193.5° , and is sparingly soluble in cold water. The *calcium salt* crystallises with 1 mol. H_2O , is more soluble in cold water than in hot, and crystallises in beautiful needles on heating the cold saturated solution in a sealed tube. It is easily soluble in cold water, less readily in absolute alcohol, and separates from the latter in aggregates of small needles.

On examining the mother liquors of the crude barium propylideneacetate, the authors separated a salt which they identified as barium ethylidenepropionate; and they point out that this explains the formation of a small quantity of lactone, observed by Zincke and Küster on boiling the bromovaleric acid obtained from their propylideneacetic acid with water.

The authors have also prepared the dibromides from the three isomeric acids, allylacetic acid, ethylidenepropionic acid, and propylideneacetic acid.

Dibromallylacetic acid is easily obtained solid, melts at 58° , is easily soluble in carbon bisulphide, more sparingly in petroleum, and crystallises from the latter in small, lustrous leaflets.

The dibromides from the other two isomerides were at first oils; but after some time the dibromide from ethylidenepropionic acid solidified, and on adding a crystal of this to the dibromide from propylideneacetic acid it also solidified. Both dibromides crystallise in large, broad needles from carbon bisulphide, and in large, measurable prisms from petroleum. They both melt at 64–65°, and are identical in crystalline form and in all other properties. E. C. R.

Polymerides of Ricinoleic Acid. By SCHEURER-KESTNER (*Compt. rend.*, 113, 201–203).—Castor oil, when heated with water at 150°, splits up into glycerol and a mixture of ricinoleic and diricinoleic acids in about equal molecular proportions. The degree of polymerisation increases with the temperature, the molecular weight of the acid being 709 after heating at 200°. As the molecular weight increases, the energy of the acid function decreases, diricinoleic acid showing a feeble neutralising power. The polyricinoleic acids are depolymerised when heated with sodium hydroxide solution at a temperature above 100°, but very little change takes place below 100°.

When ricinoleic acid is heated alone, it gradually polymerises, and finally yields pentaricinoleic acid with a molecular weight of 1418.

C. H. B.

Solid Product of the Oxidation of Drying Oils. By A. LIVACHE (*Compt. rend.*, 113, 136–139).—When the product of the oxidation of drying oils is placed in various solvents there is no apparent action, but after prolonged contact the product becomes more transparent and swells up, whilst at the same time the liquid becomes coloured. These phenomena are best seen when benzene is used. If the oxidised oil is triturated with one of the solvents, it rapidly swells up and becomes so finely divided that it forms a paste. If an excess of solvent is added, the particles composing the paste quickly become suspended in it. By trituration with successive quantities of the solvent until the latter no longer becomes coloured, the substance is separated into two parts, one soluble and coloured, the other insoluble, transparent, and gelatinous. If the gelatinous matter is allowed to dry, it forms an elastic and readily friable solid. When the solvent is allowed to evaporate, it leaves a sticky residue which welds at low temperatures. It is evident that the product of the oxidation of drying oils is very similar to caoutchouc. Solvents separate both of them into an insoluble and a soluble portion, and if the liquid is allowed to evaporate, the dissolved matter acts as a cement and forms a residue that is seemingly homogeneous. Oxidised oil can be prepared in large quantities by allowing oil to drop on sheets of cloth hung vertically, so that a very thin layer is exposed to the action of the air, oxidation taking place more rapidly if the room containing the cloths is heated. When the oxidised oil is triturated with a solvent and the solvent is allowed to evaporate, a residue is obtained that may be used in place of indiarubber for many purposes. C. H. B.

Preparation of Lactic Acid. By G. JACQUEMIN (*Bull. Soc. Chim.*, [3], 5, 294–298).—A wort is made by mashing malt at 50° and completing the exhanstion at successive temperatures of 60°, 63°,

and 65°; finally the wort is boiled, cooled to 45°, and a carbonate is added with the pure lactic ferment. Pure cultivations of the latter are made in barley wort to which calcium carbonate is added. The fermentation is carried out in vessels which are maintained at 45° by means of steam coils or hot-water pipes; the vessel should either be hermetically closed and furnished with a gas siphon, or covered with a double cloth in order to allow the escape of carbonic anhydride and prevent entrance of dust; a tube is also arranged by which filtered air is introduced to the base of the vessel once or twice during the day in order to agitate the liquor. The fermentation is complete after a lapse of five or six days.

The resulting solution of calcium lactate is freed from nitrogenous matters by the addition of tannic acid or of a tannin extract, and crystalline calcium lactate is obtained on evaporation of the filtrate. T. G. N.

Dehydracetic Acid. By D. TIVOLI (*Gazzetta*, 21, 414—420).—When a mixture of dry dehydracetic acid (50 grams) and lime (250 grams) is distilled, a brown oil (20 grams) is obtained, which on redistillation from lime and fractionation yields acetone, mesityl oxide, and parametaxyleneol, $C_8H_8Me_2 \cdot OH$, melting at 62.5° and boiling at 225° (compare Abstr., 1878, 411; 1884, 737).

The formation of an aromatic compound directly from dehydracetic acid, in this manner, being difficult to understand, the author suggests that the xyleneol may be a condensation product of the acetone. By the action of lime on acetone, Fittig (*Annalen*, 110, 32; 112, 311) obtained a substance melting at 28° and boiling at 210—220° to which he assigned the formula $C_8H_{14}O$, and the name phorone. The author, on preparing this substance, only obtained it in very small quantity, but suspects it to be xyleneol. W. J. P.

Homologues of Malic Acid. By A. MICHAEL and G. TISSOT (*Ber.*, 24, 2544—2546).—In a recent paper, Bischoff states that Fittig has obtained ethylmethylemaleic anhydride by the action of pyruvic acid on pyrotartaric acid. The authors, in the course of their work on the homologues of malic acid, have also obtained this compound synthetically, and therefore communicate part of their results, although the investigation is not yet completed.

In order, first of all, to settle the question of the constitution of citramalic acid, the authors have prepared methoxysuccinic acid, which, according to Morris (Abstr., 1880, 6) and Bredt (Abstr., 1882, 162), is not identical with the first-named acid. They find, contrary to Bredt's statement, that the acid may be readily obtained by the action of nascent hydrogen cyanide on ethyl acetoacetate, and that it melts at 119° instead of 106°. Citramalic acid prepared by Morawski's method also melted at 119°, and behaved in exactly the same manner as methoxysuccinic acid, so that the two acids must be identical.

Symmetrical ethylmethylemalic acid may be readily obtained in a similar manner from ethyl ethylacetoacetate, and forms hygroscopic prisms, melts at 132°, and yields well crystallised salts. When

heated, it passes almost quantitatively into ethylmethylemaleic anhydride, which boils without decomposition at 226° , dissolves only slightly in water, and yields salts of ethylmethylemaleic acid with alkalis. On the addition of acids to aqueous solutions of the salts, the anhydride is reprecipitated as an oil.

Pyrocinchonic anhydride may be obtained in like manner from ethyl methylacetoacetate, and the authors are at present engaged on the further investigation of this compound. They also find that the β - γ -dicarboxyl- γ -valerolactone described by Rach (Abstr., 1886, 1012) may be readily obtained from the products of the hydrolysis of the cyanhydrin of ethyl acetosuccinate, and that the tribasic potassium salt obtained by boiling it with potash loses water on heating at 150° in a vacuum, forming an acid which may be identical with cinchonic acid.

H. G. C.

Thermochemistry of Humic Acid from Sugar. By BÉRIHELOT and ANDRÉ (*Compt. rend.*, 112, 1237—1245).—Humic acid from sugar (this vol., p. 1089), prepared by separation from its alkali salts, and dried rapidly at a low temperature, had a composition agreeing with the formula $2C_{15}H_{16}O_7 + C_{18}H_{14}O_6$. Its heat of combustion was 5880 cal. at constant volume; consequently the heat of formation at constant pressure is 731 cal. for 1 gram. If the oxygen united with the hydrogen to form water, and the latter combined with the carbon and the surplus of hydrogen, the formation of the humic acid would absorb 628 cal.

Now $C_8 + C_6H_2O = C_8H_{12}O_6$ absorbs -109.1 Cal., and hence the conversion of $3C_8H_{12}O_6$ into $C_{18}H_{16}O_7$ is accompanied by the liberation of about $+110$ Cal.

Humic acid dried at about 100° swells up, forms a pasty mass in contact with water, but dissolves to a very slight extent only. There is, however, a considerable development of heat; $C_{18}H_{14}O_6 + H_2O = C_{18}H_{16}O_7$ develops $+13.7$ Cal., the heat of hydration of acetic anhydride being $+13.9$. It is remarkable that the acid tends to lose water and pass into the anhydride even at the ordinary temperature.

Humic acid is tribasic; neutralisation by the first equivalent of potassium hydroxide develops $+18$ Cal., and the salt formed is insoluble and highly stable. Addition of a second and third equivalent of alkali develops a further quantity of $+6$ Cal., with formation of bi-basic and tribasic salts. Freshly precipitated humic acid, when left in contact with its mother liquor, rapidly passes into the same condition as the air-dried acid.

Humic compounds, similar to those which exist in soils, attain their maximum degree of hydration in presence of alkalis, being dehydrated in presence of acids.

C. H. B.

A Furfurallevulinic Acid. By A. LUDWIG and E. A. KEHRER (*Ber.*, 24, 2776—2778).—When a solution of levulinic acid (23.2

grams) in water (300 c.c.) and one of sodium hydroxide (16 grams) in water (160 c.c.) are successively added to furfuraldehyde (19.2 grams) dissolved in 99 per cent. alcohol (200 c.c.), and the mixture is heated for five minutes at 60°, then cooled with ice and carefully acidified with hydrochloric acid, a precipitate is produced which is found to consist of a crystalline and a pulverulent compound; these are mechanically separated. The former is purified by crystallisation from hot ether, and forms faintly yellowish-coloured prisms, having the composition of a *furfurallevulinic acid*, $C_{10}H_{10}O_4$; it is very sparingly soluble in cold water and boiling light petroleum, readily soluble in hot alcohol or ether, and very easily in chloroform and benzene. The *silver salt*, $C_{10}H_9O_4Ag$, is not very sensitive towards light; the *calcium salt*, $(C_{10}H_9O_4)_2Ca + 2H_2O$, crystallises in yellow needles. The acid melts at 113° without perceptible decomposition, but after resolidification at 8–9° lower, having in fact then the same melting point as the above-mentioned pulverulent compound, which appears to be an isomeride, and seems also to be produced when the furfurallevulinic acid is crystallised from boiling water; this may be due to the fact that in the latter operation the acid melts prior to dissolving. Further experiments are in progress. A. R. L.

Decomposition Products of α -Hydroxy-acids. By H. v. PÉCHMANN (*Annalen*, 264, 261–303).—An exhaustive investigation of coumalinic acid, a compound obtained by treating malic acid with concentrated sulphuric acid (compare Abstr., 1884, 1124), has proved conclusively that it is a derivative of an unsaturated lactone (coumalin), and that its constitution is expressed by the formula

Coumalinic acid is best prepared by heating anhydrous malic acid (50 grams) on the water-bath with a mixture of concentrated sulphuric acid (75 grams) and 10–12 per cent. anhydrosulphuric acid (75 grams); when the evolution of carbonic oxide ceases, which is usually the case in 1½–2 hours, the solution is carefully mixed with ice (200 grams), kept over night, the precipitated acid separated by filtration, washed with ice-cold water until almost free from sulphuric acid, and then dried on porous plates; the acid in the mother liquors and washings is extracted by shaking six times with ether. The total yield of the crude product is about 80 per cent. of the theoretical, but it contains fumaric acid and traces of trimesic acid; it can be purified by dissolving it in water at 70–80°, shaking the solution with animal charcoal, and then extracting the acid with ether. It crystallises from methyl alcohol and glacial acetic acid in colourless prisms, turns reddish at 200°, and melts at 205–210° with decomposition; it boils at about 218° under a pressure of 120 mm. with partial decomposition, and when heated carefully it gives a sublimate the edges of which have a characteristic rose-colour. It is insoluble in chloroform, benzene, and light petroleum, and only sparingly soluble in cold water, ether, acetone, and ethyl acetate, but moderately easily in methyl alcohol, glacial acetic acid, and alcohol;

its solution in water and dilute acids undergoes decomposition on boiling, with evolution of carbonic anhydride and formation of crotonaldehyde, the solution turning brown. When boiled with barium hydroxide, it is decomposed into formic acid and glutaric acid (m. p. 132—134°). It is decomposed by cold alkalis, and it reduces Fehling's solution and ammoniacal silver nitrate solution (in presence of soda) on boiling; with boiling acetic anhydride, it gives an intense, brownish-red coloration. Small quantities of coumalinic acid are most easily detected by converting the acid first into the methyl salt, and then into the characteristic anil (m. p. 140°) previously described (*loc. cit.*); this reaction can be carried out with as small a quantity as 0.02 gram of the acid, if it is not very impure. All the salts of coumalinic acid are decomposed on boiling with water, yielding a carbonate and crotonaldehyde. The *magnesium* salt, $(C_6H_5O_2)_2Mg + 6H_2O$, crystallises from warm water in colourless prisms; the *zinc* salt ($+ 6H_2O$) also crystallises very well. The *barium* salt, $(C_6H_5O_2)_2Ba + 2H_2O$, is a slightly coloured, crystalline powder, more readily soluble than the salts just described. The *silver* salt is colourless, but turns black on exposure to light in a dry condition. The *mercurous* salt is a colourless, granular compound. The salts of the alkalis are very readily soluble in water, but more sparingly in alcohol. A 5 per cent. solution of the barium salt gives precipitates with ferric chloride and with bismuth nitrate, but not with solutions of copper, cadmium, lead, manganese, or mercuric salts. The methyl salt (*loc. cit.*) boils at 178—180° under a pressure of 60 mm., and at 250—260° under the ordinary atmospheric pressure without appreciable decomposition; it crystallises well from hot water, &c., melts at 73—74°, and is decomposed by water and alkaline carbonates (see below). The *ethyl* salt, $C_6H_5O_2Et$, prepared by treating the acid with alcohol and sulphuric acid, melts at 36°, boils at 262—265°, and resembles the methyl salt in its behaviour with solvents; when treated with aniline, it is converted into a yellow, crystalline *anil*, which melts at 121°. The *chloride*, $C_6H_5O_2COCl$, is formed when crude coumalinic acid is moistened with phosphorus oxychloride, and then warmed with phosphorus pentachloride on the water-bath, an energetic reaction taking place; it boils at about 180° under a pressure of 80 mm., and the distillate solidifies on cooling to a mass of crystals, which could not, however, be obtained free from phosphorus.

The formation of coumalinic acid from malic acid is due to the intermediate production of formylacetic acid; this is proved by the fact that ethyl sodioformylacetate (compare Wislicenus, *Abstr.*, 1888, 129) is readily converted into coumalinic acid on treatment with concentrated sulphuric acid. The sodium derivative just referred to is without doubt a derivative of ethyl formylacetate, as, when treated with resorcinol in presence of sodium ethoxide, it yields umbelliferon, just as resorcinol and ethyl acetoacetate give β -methylumbelliferon.

β -Nitrosopropionic acid (*oximidoformylacetic acid*),

is obtained when dilute (1 : 5) soda (140—150 c.c.) is gradually added

to a well-cooled mixture of coumalinic acid (20 grams), hydroxylamine hydrochloride (20 grams), and water (100 c.c.), and the solution then carefully warmed on the water-bath for 10–20 minutes; after cooling, sulphuric acid is added until the solution colours tropæoline paper violet, and the product is then extracted with ether. It separates from ether in colourless crystals, melts at 117–118° with decomposition, and is readily soluble in water and alcohol, but only sparingly in ether, and insoluble in chloroform, benzene, and light petroleum; it is decomposed by sodium carbonate and by boiling water, with evolution of carbonic anhydride, and it reduces Fehling's solution and ammoniacal silver nitrate solution on warming. In its aqueous solution, copper acetate produces a light-blue, crystalline precipitate, and ferric chloride a reddish-brown coloration; when warmed with acetic chloride in ethereal solution, it is converted into a compound which crystallises in colourless prisms, melts at 144–145° with decomposition, and gives a wine-red coloration with an alcoholic solution of ferric chloride. When the acid is kept for a long time, it is transformed into a porous, hygroscopic substance, which is insoluble in ether and alcohol. The molecular weight of β -nitrosopropionic acid was determined by Raoult's method, and found to be in accordance with the molecular formula given above; that it has the constitution assigned to it is proved by the following facts:—1. When boiled with dilute sulphuric acid, it is decomposed into hydroxylamine, acetaldehyde, and carbonic anhydride. 2. On reduction, it is converted into β -amidopropionic acid (β -alanine), which can be easily isolated in the form of the sulphone described below.

The most plausible explanation of the formation of β -nitrosopropionic acid from coumalinic acid is that the latter is first converted into formylglutaconic acid, $\text{COOH}\cdot\text{CH}\cdot\text{CH}\cdot\text{CH}(\text{CHO})\cdot\text{COOH}$, by direct combination with 1 mol. H_2O ; this hypothetical intermediate product probably undergoes intramolecular change into a compound of the constitution $\text{COOH}\cdot\text{CH}_2\cdot\text{CH}\cdot\text{C}(\text{CHO})\cdot\text{COOH}$, which is then decomposed into 2 mols. of formylacetic acid by combination with a second molecule of water.

Benzenesulphone- β -alanine, $\text{SO}_2\text{Ph}\cdot\text{NH}\cdot\text{CH}_2\cdot\text{CH}_2\cdot\text{COOH}$, is obtained when β -nitrosopropionic acid is reduced with sodium amalgam, and the crude product shaken with soda and benzenesulphonic chloride; it crystallises from water in colourless plates or prisms, melts at 111–112°, and is readily soluble in most ordinary solvents except cold water.

Methyl dihydrogen trimesate, $\text{C}_{10}\text{H}_8\text{O}_6$, is easily obtained by treating methyl coumalinate with dilute soda (1 mol.) at the ordinary temperature, and then acidifying the solution; on keeping for a long time, the product is deposited in colourless prisms, and can be recrystallised from boiling water. The yield is 30–40 per cent. of the methyl coumalinate employed. It crystallises with 1 mol. H_2O , which is expelled at 105°, melts at 205–208°, and is readily soluble in alcohol and ether. When methyl coumalinate is kept for some days in contact with water, it is partially transformed into methyl dihydrogen trimesate; free coumalinic acid, on the other hand, seems not to give trimesic acid, even on treatment with alkalis. Trimesic

acid melts at about 345—350° (in an air-bath); its ethyl salt crystallises in long, lustrous prisms melting at 133°, and the methyl salt in slender, lustrous needles melting at 144°.

Coumalin, $\text{CH} \begin{smallmatrix} \text{CH} \cdot \text{CO} \\ \text{CH} \cdot \text{CH} \end{smallmatrix} > \text{O}$, can be obtained by the dry distillation of mercurous coumalinate in an atmosphere of hydrogen; the yield is about 30 per cent. of the theoretical. It is a colourless oil of sp. gr. 1.20006, 19.5°/4°, but it gradually darkens on exposure to the air; it solidifies on cooling to a mass of crystals which melt at 5°. It boils at 120°, under a pressure of 30 mm. without decomposition, and under the ordinary atmospheric pressure (717 mm.) at 206—209° with slight decomposition; it is miscible with all ordinary solvents, but it separates from its aqueous solution on the addition of potassium carbonate. It is not acted on by boiling water, but it is decomposed by alkalis with formation of crotonaldehyde and carbonic anhydride.

F. S. K.

Orthocyanobenzyl Chloride and Orthocyanobenzal Chloride. By A. DRORY (*Ber.*, 24, 2563—2574).—Gabriel and Day (*Abstr.*, 1890, 1249), by the action of concentrated sulphuric acid on orthocyanobenzyl thiocyanate, have obtained a compound, $\text{C}_6\text{H}_7\text{NS}$, which behaves both like a mercaptan and like a base. The author has examined the corresponding selenium compounds.

Orthocyanobenzyl selenocyanate, $\text{CN} \cdot \text{C}_6\text{H}_4 \cdot \text{CH}_2 \cdot \text{SeCN}$, is obtained by mixing an alcoholic solution of orthocyanobenzyl chloride with an alcoholic solution of potassium selenocyanate, and heating the mixture in a reflux apparatus for $\frac{1}{4}$ — $\frac{1}{2}$ hour. It crystallises from benzene in compact, colourless, rhombohedra or prisms, melts at 121°, completely decomposes at 200°, and is soluble in methyl and ethyl alcohol, ether, petroleum, carbon bisulphide, acetone, and benzene.

Selenophthalimidine (orthocyanobenzyl selenomercaptan), $\text{C}_6\text{H}_7\text{NSe}$, is obtained by gradually adding orthocyanobenzyl selenocyanate (10 grams) to concentrated sulphuric acid (75 c.c.). Carbonic anhydride is evolved, and a clear solution is obtained. The mixture is poured into iced water, excess of sodium carbonate added, and the resulting emulsion extracted with ether. The product is a yellow oil, has a nauseous odour, partially solidifies on remaining in a closed vessel and melts again at 30°. It is soluble in chloroform, petroleum, benzene, alcohol, and ether, decomposes on exposure to air, yielding orthocyanobenzyl diselenide, and cannot be distilled without decomposition. It dissolves completely in acids, is precipitated from solution by alkalis, and is again dissolved by excess of alkali. The salts of selenophthalimidine crystallise well from alcohol in prismatic needles, and are decomposed on evaporating the aqueous solution on the water-bath. The *hydrochloride* is sparingly soluble in water and alcohol, and is obtained in long, flat, prismatic needles by evaporating an aqueous solution in a vacuum over sulphuric acid. The *platinichloride* is precipitated as an orange-yellow, insoluble, and infusible powder. The *picrate* is obtained as an intensely yellow, crystalline precipitate, is sparingly soluble in alcohol, and decomposes at 170° without melting. The *hydrobromide* crystallises in colourless, prismatic needles, and melts at 264°. The *sulphate* crystallises from

water in slender, silky needles, melts at $145-150^{\circ}$ with frothing, and, on boiling its aqueous solution, decomposes yielding selenophthalide.

Selenophthalimidine periodide, $C_6H_5NSel_2$, is obtained by heating orthocyanobenzyl selenocyanate (5 grams) with hydriodic acid (20 c.c.; sp. gr. = 1.70) for five hours at 100° . The product is washed with ether and crystallised from alcohol. It crystallises in slender, dark-violet needles, melts at 223° with decomposition, and is sparingly soluble in boiling alcohol, and almost insoluble in all other solvents.

Orthocyanobenzyl methyl selenide, $CN \cdot C_6H_4 \cdot CH_2 \cdot SeMe$, is obtained by the action of methyl iodide (2 grams) on a solution of selenophthalimidine hydrochloride (4 grams) in alcoholic potash. The product is distilled with steam and extracted with ether. It is a yellowish-brown oil, has an unpleasant odour, and distils at $180-200^{\circ}$ without decomposition.

Orthocyanobenzyl diselenide, $(CNC_6H_4 \cdot CH_2)_2Se_2$, is obtained when a solution of a salt of the compound C_6H_5NSe is treated with sodium hydroxide and extracted with ether. It crystallises in needles, melts at $108-110^{\circ}$ with decomposition, and is soluble in methyl and ethyl alcohol, benzene, chloroform, and carbon bisulphide.

Selenophthalide, $C_6H_4 \begin{smallmatrix} CH_2 \\ CO \end{smallmatrix} Se$, is obtained on allowing an alcoholic solution of selenophthalimidine to remain with excess of potash in a warm place; ammonia is slowly evolved, and on distilling the mixture in a current of steam an emulsion is obtained which deposits short, nacreous needles of selenophthalide. It crystallises from alcohol in short, colourless leaflets, melts at 58° , and is soluble in alcohol, ether, and benzene.

When orthocyanobenzyl chloride is heated to boiling in a reflux apparatus with copper nitrate and water, the blue colour of the solution remains unaltered; the chloride, however, completely dissolves, and on extracting the solution with ether, phthalide is obtained. Silver nitrate has the same action. Gabriel and Otto, however, obtained phthalide by the action of water alone on orthocyanobenzyl chloride (Abstr., 1887, 1035), and the author points out that as the colour of the above copper solution remains unaltered, the metallic salts are probably without action, and the water alone is necessary.

Orthocyanobenzyl bromide, $CN \cdot C_6H_4 \cdot CH_2Br$, is obtained by leading bromine vapour, by means of a stream of carbonic anhydride, into boiling orthotolunitrilo. It is easily soluble in alcohol, ether, benzene, petroleum, &c., sparingly in water, is volatile with steam, melts at 76° , distils without decomposition, and crystallises in the monosymmetric system, $a:b:c = 1.5363:1:0.9642$; $\beta = 78^{\circ} 5'$.

Orthophthalaldehydic acid (m. p. 96°) is obtained when orthocyanobenzal chloride (2 grams) is heated in a reflux apparatus with silver nitrate (4 grams) and water (150 c.c.).

Orthocyanotriphenylmethane is obtained as follows:—Aluminium chloride (7 grams) is gradually added to a mixture of orthocyanobenzal chloride (10 grams), and benzene (40 grams), and the mixture heated on the water-bath as long as hydrogen chloride is evolved. The mixture is then treated with dilute hydrochloric acid, and the layer of benzene which contains the product diluted with ether, separated,

dried with calcium chloride, and distilled. After the ether, benzene, and benzal chloride have distilled, an oil is obtained which distils at 270—285° under 20—30 mm. pressure. It is dissolved in absolute alcohol, decolorised with animal charcoal, and allowed to crystallise. It forms slender, white needles, melts at 89°, and is soluble in methyl and ethyl alcohol, ether, chloroform, acetic acid, and benzene, insoluble in petroleum and water. When hydrolysed with 25 per cent. alcoholic potash, it yields *triphenylmethaneorthocarboxylic acid*; this crystallises from acetic acid in slender, white needles, softens at 158°, and melts at 162°.

Orthocyanocinnamic acid, $\text{CN}\cdot\text{C}_6\text{H}_4\cdot\text{CH}\cdot\text{CH}\cdot\text{COOH}$, is obtained by heating cyanobenzal chloride (2 parts) with dry sodium acetate (1 part) and acetic anhydride (10 parts) for 10 hours at 180°. The product is neutralised with sodium carbonate, the unaltered benzal chloride removed by distilling with steam, and the filtered solution precipitated with hydrochloric acid. It crystallises from alcohol in slender, colourless needles, melts at 252°, is soluble in alcohol, ether, acetic acid, chloroform, and benzene, but insoluble in water.

E. C. R.

Preparation of 1 : 2 : 4- and 1 : 3 : 4-Dichlorotoluenes. By H. ERDMANN (*Ber.*, 24, 2769—2771).—1 : 2 : 4-Dichlorotoluene [$\text{Me} : \text{Cl}_2 = 1 : 2 : 4$] is best prepared from metatolylenediamine by Sandmeyer's method. A solution of 200 grams of cupric chloride in a litre of hydrochloric acid (sp. gr. = 1.175) is boiled with 150 grams of copper turnings until decolorised, then mixed with a solution of 1 kilo. of metatolylenediamine in a litre of hydrochloric acid diluted with a litre of water, and, without cooling, treated with about 9 litres of a 10 per cent. sodium nitrite solution added in a thin stream with constant stirring. The dichlorotoluene, which separates as a heavy, black oil, is steam-distilled, and freed from phenols and azo-derivatives by washing with aqueous soda, drying over solid potash, and afterwards distilling. The yield amounts to 45 per cent. of the theoretical. Pure 1 : 2 : 4-dichlorotoluene boils at 196—197.5° (compare Lellmann and Klotz, *Abstr.*, 1886, 452).

1 : 3 : 4-Dichlorotoluene [$\text{Me} : \text{Cl}_2 = 1 : 3 : 4$] can be prepared from metachloracetoparatoluidide by converting it into the crude hydrochloride (this vol., p. 1466), and treating this by Sandmeyer's method. The yield of dichlorotoluene from 1 kilo. of paratoluidine by this method was found to be 320 grams.

W. P. W.

Artificial Mineral Lubricating Oil. The Condensation Products of Allyl Alcohol with Methylbenzenes. By G. KRAEMER and A. SPILKER (*Ber.*, 24, 2785—2793).—In a previous communication (this vol., p. 206), the authors have described the compounds obtained by the condensation of cinnamene with toluene, xylene, and pseudocumene, and were led to regard them as derivatives of propane. The investigations of Koenigs (this vol., p. 208), and of Liebermann and Hartmann (this vol., p. 1484), however, make it more probable that the compounds in question are ethane derivatives, the methyl radicals in the benzene ring taking no part in the condensation. Xylene

cinnamene, previously described as phenyltoluylpropane, must, therefore, be regarded as phenylxylylethane, $\text{CHMePh}\cdot\text{C}_6\text{H}_4\text{Me}_2$. At the time the paper on the condensation of cinnamene with xylene was read, the hope was expressed that some light would soon be thrown on the obscure problem of the formation of lubricating oils from petroleum, on account of the resemblance between these oils and cinnamene derivatives, as evidenced not only by the behaviour towards chemical reagents, but also by the fact that cinnamene derivatives containing methyl radicles in the benzene ring exhibit the property of viscosity in a marked degree. For example, phenylxylylethane has a viscosity of 2.1, compared with the value 15 for a medium lubricating oil from Alsatian petroleum, and a value 35 for a good lubricating oil from Caucasian petroleum.

The present paper deals with the condensation of methylbenzene with allyl alcohol in the presence of sulphuric acid. To bring about the condensation, a mixture of 100 c.c. of pure concentrated sulphuric acid and 50 c.c. of fuming sulphuric acid is gradually added, with vigorous shaking, to a mixture of 100 c.c. of anhydrous allyl alcohol with 1000 c.c. of pseudocumene (xylene, &c.), and precautions are taken against rise of temperature during the reaction. After remaining for some time, the sulphuric acid is carefully separated from the oil, and the latter mixed with a few drops of water to remove the remainder of the acid, and afterwards successively washed with dilute acid, three to four times with water in quantities of 100 c.c., then with 5 per cent. aqueous soda to alkaline reaction, and finally with water until neutral. During the washing, a difficulty arises from the tendency of the two layers to form a stable, white emulsion—a well-known and dreaded occurrence in the manufacture of lubricating oil; this can, however, be overcome by the addition of ether. The oil, after washing, is freed from pseudocumene (xylene, &c.) by a current of steam at 110 – 120° ; the temperature is then raised, and at 200 – 220° a thick, colourless oil passes over with the steam, leaving a yellowish-brown, resinous substance, which very slowly distils with steam at 250° , and can be purified by fractionally distilling with steam, extracting with ether, &c.

The thick, colourless oil obtained from pseudocumene can be purified by again distilling with steam at about 200° , or better by distillation in a vacuum. It has the composition $\text{C}_{21}\text{H}_{28}$, giving by Raoult's method numbers which agree well with this formula, and is probably a *dimethyldicumylmethane*. In the pure state it boils above 300° at the ordinary pressure, without appreciable decomposition, and in the viscosimeter gives at 15° the value 775 (water = 1), whilst the best Russian lubricating oil gives the value 40 in the same apparatus. The resinous product of the reaction has the composition $(\text{C}_{21}\text{H}_{28})_n$, and by Raoult's method gives as a mean of two determinations the value 763 for the molecular weight. The yields from 100 c.c. of allyl alcohol were 122 grams of oil and 90 grams of resin, and from 50 c.c. of alcohol, 52 grams of oil and 50 grams of resin.

The oily product of the condensation of allyl alcohol with xylene has the composition $\text{C}_{15}\text{H}_{24}$, as confirmed by a determination of the molecular weight by Raoult's method. It is significantly less viscous

than the corresponding product (containing two additional methyl radicles) from pseudocumene, and gives the value 8.1 in the same viscosimeter. The yield from 100 c.c. of allyl alcohol amounted to 88 grams of oil and 50 grams of resin.

As a necessary consequence, it would follow that all high boiling fractions of petroleum are free from oxygen, and that the lubricating oils are poorer in hydrogen than the less viscous paraffin oils. These conclusions are borne out by analyses of a commercial lubricating oil of Caucasian origin, and a paraffin oil (viscosity = 15) from Alsatian petroleum. The investigation is being continued, but on account of the difficulty of characterising the products, rapid progress is not to be expected.

W. P. W.

Artificial Musk. By A. BAUR (*Ber.*, 24, 2832—2843).—The artificial musk described in a previous communication (*Abstr.*, 1890, 1401) was regarded as trinitroisobutyltoluene. It is, however, a derivative, not of isoprimary but of tertiary butyltoluene, owing to the occurrence in the preparation of the hydrocarbon of an intramolecular change, corresponding with that observed by Schramm in the case of the condensation of benzene with isobutyl bromide by the Friedel-Crafts method (*Abstr.*, 1889, 127).

Tertiary butyltoluene is easily obtained by the action of tertiary butyl chloride on toluene in the presence of aluminium chloride. It boils at 185—187°, and agrees in properties with the so-called isobutyltoluene. The *sulphonic acid*, prepared by warming it with concentrated sulphuric acid, forms a *barium salt*, $(C_{11}H_{15}SO_3)_2Ba + H_2O$, which crystallises in white scales, and dissolves sparingly in cold water, but more easily in hot water, and in 50—60 per cent. alcohol. The *sulphonamide*, $C_{11}H_{15}SO_2NH_2$, crystallises from water in nacreous scales, and melts at 94—95°. Earlier determinations with the sulphonamide prepared from so-called isobutyltoluene gave 74—75° as the melting point, and this value is always obtained with the freshly-prepared substance; after being kept for some hours, the melting point is found to have risen to and remains constant at 94—95°. The trinitrobutyltoluene formed by the nitration of tertiary butyltoluene melts at 96—97°, and is identical with the product from so-called isobutyltoluene.

Nitrobutyltoluene, $CMe_3C_6H_4MeNO_2$, is obtained by slowly adding fuming nitric acid to a solution of tertiary butyltoluene in acetic acid. It is a yellowish oil of a peculiar and slightly unpleasant odour, boils at 160—162° in a vacuum without decomposition, and is readily volatile with steam. On treatment with excess of nitric acid, it is converted into artificial musk.

Dinitrobutyltoluene, $CMe_3C_6H_4Me(NO_2)_2$, is formed, together with the mononitro- and trinitro-derivatives when tertiary butyltoluene is dissolved in well-cooled nitric acid of sp. gr. 1.5. On distillation with steam, the mononitro-derivative passes over first, and then a mixture of the mononitro- and dinitro-derivatives distils over, leaving a residue of the trinitro-derivative mixed with a very small quantity of the dinitro-compound. A separation of the dinitrobutyltoluene can be more easily effected by crystallising out the greater part of the

trinitrobutyltoluene, repeatedly distilling the oil in a vacuum, and collecting the fraction boiling at 224—225°. Dinitrobutyltoluene is a brown oil of very unpleasant odour, and does not solidify in a freezing mixture. On further nitration, it is converted into artificial musk.

Trinitrobutyltoluene (artificial musk), $\text{CMe}_3\cdot\text{C}_6\text{HMe}(\text{NO}_2)_3$, is obtained when tertiary butyltoluene is slowly added in the cold to five times its weight of a mixture of 1 part of nitric acid (sp. gr. = 1.5) and 2 parts of 15 per cent. anhydrosulphuric acid, and the mixture afterwards heated for 8—9 hours on a water-bath. It crystallises from alcohol in yellowish-white needles, melts at 96—97°, is only very slightly volatile with steam, and has a powerful odour of musk. It is insoluble in water, but it dissolves readily in alcohol, ether, benzene, chloroform, and light petroleum. With naphthalene in alcoholic solution, it forms a compound $2\text{C}_{11}\text{H}_{13}(\text{NO}_2)_3\cdot\text{C}_{10}\text{H}_8$, which crystallises in large, yellowish scales, melts at 89—90°, and decomposes into its generators on warming with water. Trinitrobutyltoluene is not affected by treatment with alkalis or ammonia, and when warmed with an excess of aniline forms a compound $3\text{C}_{11}\text{H}_{13}(\text{NO}_2)_3\cdot 2\text{NH}_2\text{Ph}$, which crystallises from the excess of aniline in compact forms, and melts at 64°. Of the four possible formulæ for a trinitrometabutyltoluene, the author, on these grounds, excludes the three containing two nitro-radicles relatively in the ortho-position, and assigns to artificial musk the remaining formula

Amidobutyltoluene, $\text{CMe}_3\cdot\text{C}_6\text{H}_2\text{Me}\cdot\text{NH}_2$, is formed by the reduction of nitrobutyltoluene with tin and hydrochloric acid. It is a colourless oil, of pleasant, cumin-like odour, and boils at 245°. The acetyl derivative, $\text{C}_{11}\text{H}_{13}\cdot\text{NHAc}$, crystallises from alcohol in lustrous scales melting at 162°, and the benzoyl derivative in small, white needles melting at 167—168°. It is therefore identical with the amido-compound obtained by Effront (Abstr., 1884, 899; 1885, 152) by heating isobutyl alcohol with orthotoluidine hydrochloride at 280—300°, and must contain the amidegen in the para-position relatively to the tertiary butyl radicle.

Amidodinitrobutyltoluene, $\text{CMe}_3\cdot\text{C}_6\text{HMe}(\text{NO}_2)_2\cdot\text{NH}_2$, is obtained when trinitrobutyltoluene in alcoholic solution is reduced with the theoretical quantity of ammonium sulphide. It crystallises from alcohol in brownish-yellow needles, melts at 125—126°, and is insoluble in water. The *hydrochloride* crystallises in brown scales, and on treatment in alcoholic solution with ethyl nitrite, gives a *dinitrobutyltoluene*, which could not be crystallised.

Tertiary butylmetaxylene, $\text{C}_6\text{H}_3\text{Me}_2\cdot\text{CMe}_3$ [$\text{Me}_2 : \text{CMe}_3 = 1 : 3 : 5$], can be prepared by boiling metaxylene either with isobutyl bromide or tertiary butyl bromide in the presence of aluminium chloride. It is a colourless liquid which boils at 200—202° under 747 mm. pressure, and on oxidation with nitric acid, yields mesitylenic acid, and with chromic acid, trimesic acid. The *trinitro*-derivative, $\text{CMe}_3\cdot\text{C}_6\text{HMe}_2(\text{NO}_2)_3$, crystallises from alcohol in yellowish-white needles, melts at 110°, and has a strong, musk-like odour; the *nitro*-derivative, $\text{CMe}_3\cdot\text{C}_6\text{H}_2\text{Me}_2\cdot\text{NO}_2$,

formed by adding fuming nitric acid to a cold acetic acid solution of the hydrocarbon, crystallises from alcohol in white needles which melt at 85° , and have a cinnamon-like odour.

Butylethylbenzene, $C_8H_{10}Et.CMe_3$, is formed by the condensation of ethylbenzene and isobutyl bromide in the presence of aluminium chloride, and is separated from the butyltoluene and butylbenzene produced in the reaction by fractional distillation at $200-205^{\circ}$. It resembles butyltoluene in properties, and yields a *trinitro*-derivative, $CMe_3.C_8H_6Et(NO_2)_3$, which is more soluble in alcohol than artificial musk, and has a strong, musk-like odour.

Among the secondary products of the reaction between pure toluene and pure isobutyl bromide in the presence of aluminium chloride, are butylbenzene, butylxylene, butylethylbenzene, dibutylbenzene, and dibutyltoluene, and these substances are present in the fraction $170-200^{\circ}$, which was formerly used instead of pure tertiary butyltoluene in the preparation of artificial musk. W. P. W.

Action of Chlorine on Acetoparatoluidide. Preparation of Metachloroparatoluidine. By H. ERDMANN (*Ber.*, 24, 2766—2769).—Hitherto metachloracetoparatoluidide has been prepared by the action of chlorine on acetoparatoluidide, either suspended in water (Wroblewsky, *Annalen*, 168, 196), or in dilute aqueous solution at 0° (Lellmann and Klotz, *Abstr.*, 1886, 452), and in both cases the yield was small and unsatisfactory. It can, however, be obtained in considerable quantity by dissolving acetoparatoluidide (100 grams) in hot acetic acid (100 c.c.), and passing a rapid stream of chlorine (160 grams) through the solution, which soon becomes boiling hot. To prevent loss of chlorine, three flasks placed in series, and containing the quantities given, are connected with the chlorine generator. The metachloracetoparatoluidide can be easily freed from accompanying resinous matters, and crystallises from alcohol, or from a mixture of chloroform and light petroleum, in needles melting at $111-112^{\circ}$.

Metachloroparatoluidine may be prepared directly from the chlorination product by distilling off the acetic acid, boiling the residue with 20 per cent. hydrochloric acid in a reflux apparatus for 3—4 hours, and afterwards distilling with steam to remove the small quantity of chlorinated cresol formed in the reaction. On cooling, the sparingly soluble hydrochloride separates as a crystalline mass, whilst the more soluble paratoluidine hydrochloride remains in the mother liquor. The crystalline hydrochloride is then decomposed with aqueous soda, and the base freed from the less volatile dichlorotoluidine by steam distillation. The yield, under these conditions, amounts to more than 400 grams from 1 kilo. of commercial paratoluidine, and the product is very fairly pure, boiling at $218-225^{\circ}$. Metachloroparatoluidine, purified by conversion into its sparingly soluble crystalline nitrate, is a colourless oil which boils at $223-224^{\circ}$ (corr.), and crystallises in a freezing mixture in lustrous, snow-white scales melting at 7° ; on exposure to air and light, it soon becomes coloured. W. P. W.

γ -Phenoxypropylamine. By J. LOHMANN (*Ber.*, 24, 2631—2641).— γ -Bromopropyl phenyl ether, $\text{CH}_2\text{Br}\cdot\text{CH}_2\cdot\text{CH}_2\cdot\text{OPh}$, is formed, together with a small proportion of trimethylene diphenyl ether, when an alcoholic solution of trimethylene bromide (41 grams) and sodium phenoxide (15 grams) is heated in a reflux apparatus for about four hours on a water-bath. After removal of the alcohol by distillation, the product is steam-distilled, and the distillate extracted with ether; the residue left after evaporation of the ether is freed from phenol by extraction with dilute aqueous soda, and from trimethylene bromide by fractional distillation. The yield amounts to about 40 per cent. of the theoretical. The ether is an oil which boils at $246\text{--}256^\circ$ with decomposition, and dissolves in most solvents except water.

γ -Phenoxypropylphthalimide, $\text{C}_6\text{H}_4\text{O}_2\text{N}\cdot\text{C}_3\text{H}_6\cdot\text{OPh}$, is obtained by heating equal weights of γ -bromopropyl phenyl ether and potassium phthalimide at 220° for an hour. It crystallises from alcohol in white needles, melts at 88° , and is easily soluble in most solvents. When heated with concentrated hydrochloric acid at $180\text{--}185^\circ$ for 4—5 hours, it is decomposed into a mixture of phthalic acid, phenol, and γ -chloropropylamine hydrochloride.

γ -Phenoxypropylphthalamic acid, $\text{OPh}\cdot\text{C}_3\text{H}_6\cdot\text{NH}\cdot\text{CO}\cdot\text{C}_6\text{H}_4\cdot\text{COOH}$, is obtained by boiling γ -phenoxypropylphthalimide with dilute aqueous potash until dissolved, pouring the solution into cold water, and acidifying with hydrochloric acid. It is a white, crystalline powder which melts at 134° , is insoluble in almost all solvents except alcohol, and regenerates the imide on boiling with alcohol. When heated with 5—6 times its weight of hydrochloric acid in a reflux apparatus for about an hour, it decomposes into phthalic acid and γ -phenoxypropylamine hydrochloride. γ -Phenoxypropylamine, $\text{OPh}\cdot\text{C}_3\text{H}_6\cdot\text{NH}_2$, is a colourless oil which boils at $241\text{--}242^\circ$ under 766 mm. pressure, and readily absorbs carbonic anhydride from the air. The hydrochloride, $\text{C}_6\text{H}_5\text{NO}\cdot\text{HCl}$, crystallises from alcohol in lustrous, pale-yellow scales, and melts at 168° ; the picrate and platinochloride, $(\text{C}_6\text{H}_5\text{NO})_2\cdot\text{H}_2\text{PtCl}_6$, are crystalline. The benzoyl derivative,

crystallises from alcohol in white needles melting at 118° , and the carbamide, $\text{OPh}\cdot\text{C}_3\text{H}_6\cdot\text{NH}\cdot\text{CONH}_2$, in silvery scales melting at 114° .

γ -Diphenoxypropylamine, $(\text{OPh}\cdot\text{C}_3\text{H}_6)_2\text{NH}$, is formed, together with a small quantity of γ -phenoxypropylamine when γ -bromopropyl phenyl ether (12 grams) is digested with 10 per cent. alcoholic ammonia (15—20 c.c.) at 100° for 2—3 hours. It is an oil boiling at above 300° . The hydrochloride, $\text{C}_{12}\text{H}_{21}\text{NO}_2\cdot\text{HCl}$, crystallises from alcohol in transparent needles, melts at 206° , and is very sparingly soluble in water. The nitrosamine, $\text{C}_{12}\text{H}_{21}\text{O}_2\text{N}\cdot\text{NO}$, crystallises from alcohol in pale-yellow, lustrous scales, melts at $60\text{--}61^\circ$, dissolves readily in most solvents except water, and decomposes into γ -diphenoxypropylamine and ammonia on reduction in alcoholic solution with zinc-dust.

γ -Phenoxypropylaniline, $\text{OPh}\cdot\text{C}_3\text{H}_6\cdot\text{NHPh}$, is prepared by heating γ -bromopropyl phenyl ether (12 grams) with aniline (15 grams) for about two hours on a water-bath, and subsequently removing the

excess of aniline by steam distillation. It is a brown oil of basic odour, and boils at above 300° , dissolves in most solvents with the exception of water, and on standing solidifies to a mass which melts at 32° . The *hydrochloride*, $C_{12}H_{17}NO \cdot HCl$, crystallises from alcohol in needles, melts at 170° , and, when warmed with water, is partly dissolved and partly decomposed into the base and hydrochloric acid.

γ -Phenoxybutyronitrile, $OPh \cdot C_3H_6 \cdot CN$, is obtained when γ -bromopropyl phenyl ether (20 grams), alcohol (180 c.c.), and a solution of potassium cyanide (18 grams) in water (36 c.c.) are heated together for 3—4 hours in a reflux apparatus. It crystallises in white needles, melts at 45 — 46° , boils at 287 — 289° , and dissolves easily in the ordinary solvents. On hydrolysis with concentrated hydrochloric acid at 100° , it is converted into *γ -phenoxybutyric acid*, $OPh \cdot C_3H_6 \cdot COOH$, which crystallises from light petroleum in silvery scales, melts at 60° , and is insoluble in water, sparingly soluble in hydrochloric acid, light petroleum, and carbon bisulphide, and easily soluble in alcohol, ether, chloroform, and benzene. When dissolved in 5—6 times its weight of cold concentrated sulphuric acid, and left for 5—6 hours, the nitrile undergoes both hydrolysis and sulphonation with the production of *sulpho- γ -phenoxybutyramide*, $SO_3H \cdot C_6H_4 \cdot O \cdot C_3H_6 \cdot CONH_2$. This substance melts at 211° , can be crystallised from water, is insoluble in alcohol, benzene, chloroform, &c., and yields salts on treatment with carbonates.

Trimethylene diphenyl ether, $OPh \cdot CH_2 \cdot CH_2 \cdot CH_2 \cdot OPh$, formed as a secondary product in the preparation of γ -bromopropyl phenyl ether, crystallises from alcohol in lustrous scales, melts at 61° , does not volatilise with steam, and is readily soluble in most solvents.

γ -Phenoxypropyl alcohol, $OPh \cdot C_3H_6 \cdot CH_2 \cdot OH$, prepared by treating a hot aqueous solution of γ -phenoxypropylamine hydrochloride with a hot solution of sodium nitrite, is an oily liquid boiling at 240 — 250° under 764 mm. pressure.

Trimethylene phenyl methyl ether, $OPh \cdot C_3H_6 \cdot OMe$, is obtained when γ -bromopropyl phenyl ether is boiled with the calculated quantity of sodium methoxide in methyl alcohol solution for 2—3 hours in a reflux apparatus. It is an oily liquid boiling at 230 — 231° .

Trimethylene phenyl ethyl ether, $OPh \cdot C_3H_6 \cdot OEt$, formed by boiling γ -bromopropyl phenyl ether with alcoholic potash for two hours in a reflux apparatus, is a colourless, oily liquid of pleasant odour, and boils at 328 — 330° under 760 mm. pressure. W. P. W.

Products of the Action of Aromatic Carbodiimides on Orthodiamines. By A. KELLER (*Ber.*, 24, 2498—2525).—According to the investigations of Dahm and Gasiorowski (*Abstr.*, 1887, 247), and of Moore (*Abstr.*, 1889, 983; 1890, 246), orthodiamines combine with carbodiphenylimide and carbodiparatolylimide in molecular proportions. The author in continuing Moore's experiments has obtained results differing considerably from those of the latter investigator, and has therefore repeated the whole of the work with the following results:—

Carbodiphenylimide and orthophenylenediamine were heated

together in molecular proportion for five minutes at 210–220°, and the product, which smells strongly of aniline, distilled in a current of steam. The distillate contains aniline in considerable quantity, whilst the residue, after recrystallisation from benzene or alcohol, forms white needles or prisms, and melts at 190°. It has the composition $C_{13}H_{11}N_3$, and appears to be *phenylorthophenyleneguanidine*, its formation being represented as follows:—

It crystallises from alcohol, when the solution is allowed to evaporate slowly, in thick, apparently monosymmetric prisms, is almost insoluble in water and light petroleum, sparingly soluble in ether, and readily in alcohol. It distils with slight decomposition at 440–450°, but may be volatilised unchanged under 30 mm. pressure, and has then a vapour density corresponding with the above formula. It is a very stable substance, and is only attacked by hydrochloric acid at 300°. The *hydrochloride*, $C_{13}H_{11}N_3 \cdot HCl$, forms long, white, hair-like needles, and is soluble in water and alcohol; the *platinochloride*, $(C_{13}H_{11}N_3)_2 \cdot H_2PtCl_6$, is a pale-yellow, crystalline powder, almost insoluble in water; the *sulphate*, $(C_{13}H_{11}N_3)_2 \cdot H_2SO_4$, crystallises in long, hair-like needles, and is slightly soluble in cold, readily in hot water and in alcohol; the *acetyl* compound, $C_{13}H_{10}N_3 \cdot Ac$, is unstable, and crystallises from benzene in fascicular aggregates of prisms melting at 160°; and the *dibenzoyl* compound, $C_{13}H_9N_3 \cdot Bz_2$, crystallises in fascicular aggregates of white, lustrous needles, and melts at 171°. If the base is dissolved in acetic acid and mixed with an aqueous solution of potassium nitrite, a pale-yellow, crystalline precipitate of the *nitroso*-compound $C_{13}H_{10}N_3 \cdot NO$ is formed, which separates from all solvents as an oil, and shows Liebermann's reaction.

As the phenylorthophenyleneguanidine contains two imido-groups, it appeared probable that it would combine with phenyl isocyanate forming a double carbamide. This reaction does in all probability take place, but the product at once loses aniline, forming the compound $C_6H_5\langle\begin{smallmatrix} N \\ N \end{smallmatrix}\rangle C:NPh\begin{smallmatrix} CO \\ CO \end{smallmatrix}\rangle NPh$, which crystallises from alcohol in thin, lustrous, white needles, melts at 264–266°, is insoluble in water and light petroleum, but soluble in alcohol and benzene.

According to Moore (*loc. cit.*), 2 mols. of carbodiphenylimide also unite directly with 1 mol. of orthophenylenediamine, forming the compound $C_6H_4N_2[C(NHPh)_2]_2$; the author finds, however, that the products of the reaction are aniline, phenylorthophenyleneguanidine, and triphenylguanidine (m. p. 144°). If, on the other hand, phenylorthophenyleneguanidine is treated with a second molecule of carbodiphenylimide at 210°, the compound *diphenylamidomethylenepherylorthophenyleneguanidine*, $C_6H_5\langle\begin{smallmatrix} N \\ N \end{smallmatrix}\rangle C:NPh\begin{smallmatrix} CO \\ CO \end{smallmatrix}\rangle C(NHPh)_2$, is formed,

which crystallises from alcohol in white needles and melts at 188°, the yield is small, owing to the secondary reactions which take

place. If carbodiparatolyimide is substituted for carbodiphenylimide, the corresponding *paratolyl* derivative is obtained; it crystallises in white needles and melts at 185—187°.

Paratolylorthophenyleneguanidine, $C_6H_4 \begin{smallmatrix} \text{NH} \\ \text{NH} \end{smallmatrix} > C:N \cdot C_7H_7$, is obtained on heating together orthophenylenediamine and carbodiparatolyimide; it crystallises from alcohol in short, thick, slightly brownish tablets, melts at 209°, and dissolves readily in boiling alcohol and acetic acid, scarcely at all in water. The *hydrochloride*, $C_{14}H_{13}N_3 \cdot HCl$, forms white needles, soluble in hot water and cold alcohol; the *platinochloride*, $(C_{14}H_{13}N_3)_2 \cdot H_2PtCl_6$, is a pale-yellow, microcrystalline precipitate; the *sulphate*, $(C_{14}H_{13}N_3)_2 \cdot H_2SO_4$, crystallises in long, white needles; the *acetyl* compound, $C_{14}H_{13}N_3 \cdot Ac$, forms unstable, white needles and melts at 152°; and the *dibenzoyl* compound, $C_{14}H_{13}N_3 \cdot Bz_2$, crystallises in long, lustrous prisms, melting at 191°. The *nitroso*-compound, $C_{14}H_{13}N_3 \cdot NO$, forms yellow, crystalline flakes, and commences to decompose at 90°.

Paratolylorthophenyleneguanidine combines with phenyl isocyanate, forming the compound $C_6H_4 \begin{smallmatrix} \text{N} \\ \text{N} \end{smallmatrix} > \underline{C:NC_7H_7} \begin{smallmatrix} \text{CO} \\ \text{CO} \end{smallmatrix} > NPh$, which crystallises in small needles and melts at 252—254°. With carbodiparatolyimide, the base yields the compound

which separates from boiling alcohol in short needles melting at 187.5—188°.

Phenylorthotoluyleneguanidine, $C_7H_4 \begin{smallmatrix} \text{NH} \\ \text{NH} \end{smallmatrix} > C:NPh$, is obtained together with aniline by heating orthotoluylenediamine with carbodiphenylimide in molecular proportion. It crystallises from alcohol in short, white needles, and from benzene in prisms, and melts at 166—167°; the *hydrochloride*, $C_{11}H_{13}N_3 \cdot HCl$, forms long, white, elastic, silky needles; the *platinochloride*, $(C_{11}H_{13}N_3)_2 \cdot H_2PtCl_6 + 3H_2O$, large, orange-yellow tablets; the *sulphate*, $(C_{11}H_{13}N_3)_2 \cdot H_2SO_4$, long, white, lustrous needles; the *acetyl* compound, $C_{11}H_{13}N_3 \cdot Ac$, white needles, melting at 144—147°; the *dibenzoyl* compound fascicular aggregates of prisms, melting at 220—222°; the *nitroso*-compound, $C_{11}H_{13}N_3 \cdot NO$, is a flocculent precipitate, melting at 120—125° with decomposition. The base combines with phenyl isocyanate and carbodiphenylimide to form the compounds

melting at 230—234° and 199—200° respectively. The *diparatolyl* compound corresponding with the latter melts at 190—193°.

Paratolylorthotoluyleneguanidine, $C_7H_4 \begin{smallmatrix} \text{NH} \\ \text{NH} \end{smallmatrix} > C:N \cdot C_7H_7$, is obtained by heating together orthotoluylenediamine and carbodiparatolyimide; it crystallises from alcohol in white prisms, and melts at 197—198°. The *hydrochloride*, $C_{14}H_{15}N_3 \cdot HCl$, forms long, white, silky needles; the *platinochloride*, $(C_{14}H_{15}N_3)_2 \cdot H_2PtCl_6$, orange-coloured tablets; the

sulphate, $(C_{15}H_{15}N_3)_2 \cdot H_2SO_4 + 5H_2O$, lustrous, white needles; the *acetyl* compound, $C_{15}H_{14}N_3Ac$, long, white needles melting at $148-149^\circ$; the *dibenzoyl* compound, $C_{15}H_{13}N_3Bz_2$, fascicular aggregates of white needles melting at $198-201^\circ$; the *nitroso*-compound, $C_{15}H_{14}N_3NO$, commences to decompose at 130° .

Tolyltoluyleneguanidine combines with phenyl isocyanate, yielding the compound $C_7H_5 < \underset{N}{\overset{N}{\text{N}}} > \text{C} \cdot \text{NC}_7H_7 \begin{smallmatrix} \text{CO} \\ \text{CO} \end{smallmatrix} > \text{NHPh}$, which crystallises from alcohol in small needles, and melts at $230-233^\circ$. With carbodiparatolylimide, it forms $C_7H_5 < \underset{N}{\overset{N}{\text{N}}} > \text{C} \cdot \text{NC}_7H_7 > \text{C}(\text{NH} \cdot \text{C}_7H_7)_2$, which melts at $208-210^\circ$; the corresponding *diphenyl* compound melts at $174-176^\circ$.
H. G. C.

Anilguanidine. By G. PELLIZZARI (*Gazzetta*, 21, 330-340).—Cyanamide reacts with phenylhydrazine hydrochloride to form anilguanidine hydrochloride,

The same product is obtained by the action of phenylhydrazine on guanidine,

Anilguanidine hydrochloride, $C_7H_{10}N_4 \cdot HCl$, is obtained by boiling a solution of cyanamide (18 grams) and phenylhydrazine hydrochloride (60 grams) in alcohol (300 grams) for 12 hours; the greater part of the alcohol is then evaporated, very dilute hydrochloric acid added, and the solution allowed to cool after expulsion of the remaining alcohol. The salt separates in reddish crystals, which, on recrystallisation from water, form yellowish, acicular crystals, very soluble in hot alcohol and water, less so in hydrochloric acid. It melts with decomposition at 226° , and reduces ammoniacal silver nitrate solution. A yield of 50 per cent. is obtained by the above method; the mother liquors contain another base not yet studied. The hydrochloride may also be obtained by gradually heating guanidine carbonate with phenylhydrazine hydrochloride to 180° , the crude product being crystallised from dilute hydrochloric acid. The yield is, however, a poor one. *Anilguanidine platinochloride*, $(C_7H_{10}N_4)_2 \cdot H_2PtCl_4$, is precipitated in minute, yellowish, prismatic crystals frequently twined crosswise. It is soluble in hot water, but after a time is reduced with separation of metallic platinum. The *carbonate*, $(C_7H_{10}N_4)_3 \cdot H_2CO_3 + H_2O$, forms minute, white scales, which are slowly coloured red on exposure to the air. On heating, it loses ammonia and water, yielding a new base not yet investigated. The *acetate*, $C_7H_{10}N_4 \cdot C_2H_3O_2$, is obtained in small, colourless crystals which decompose at 195° ; it is very soluble in alcohol.

When concentrated potash is added to the solution of the hydrochloride, the free base separates in little drops, which soon solidify to

yellow, needle-shaped crystals. It changes spontaneously in air, and is obtained pure only with great difficulty.

Ethyl acetoacetate reacts with anilguanidine, forming a closed chain compound. A solution of anilguanidine hydrochloride (10 grams), ethyl acetoacetate (7 grams), and sodium carbonate (2.8 grams) in alcohol (50 c.c.) is boiled for seven hours, the alcoholic solution partly evaporated, dissolved in water, and acidified with acetic acid; on cooling, the new compound (8 grams) is obtained. By recrystallisation from alcohol, it may be obtained in white crystals of the composition $C_{11}H_{12}N_4O$, which on heating turn red and slowly decompose without melting. The reaction may be represented by the equation $C_6H_{10}O_3 + C_7H_{10}N_4 = H_2O + C_2H_5O + C_{11}H_{12}N_4O$; the product is probably
$$\begin{array}{c} \text{NH}\cdot\text{C}\cdot\text{NH}\cdot\text{CMe} \\ | \qquad | \\ \text{PhN}_2\text{H}\cdot\text{CO}\cdot\text{CH} \end{array}$$
 . The *dibromo-derivative*,

is obtained on bromination in glacial acetic acid solution, and consists of minute, colourless crystals, insoluble in water and alcohol, slightly soluble in acetic acid, and decomposing at $220-222^\circ$.

The *ethyl derivative*, $C_{13}H_{14}N_4O$, is obtained on treating anilguanidine hydrochloride with ethyl ethylacetoacetate in alcoholic solution, as spherical aggregates of short, thin, yellow prisms.

When a mixture of ethyl diethylacetoacetate and anilguanidine hydrochloride is treated as above, no reaction occurs even when the heating is continued for some days. W. J. P.

Halogenated Amines of the Fatty Series. By O. SMITZ (*Ber.*, 24, 2624—2631).—With the object of preparing chlorinated amines of the fatty series, the author has treated potassium phthalimide with various chlorobromides by Gabriel's method (*Abstr.*, 1888, 439) in the hope that the more reactive bromine would alone be eliminated with the production of chloroethyl- or chloropropyl-phthalimide. Trimethylene chlorobromide, however, yields a mixture of γ -chloropropyl- and γ -bromopropyl-phthalimide, and ethylene chlorobromide in like manner gives a mixture of chloroethyl- and bromoethyl-phthalimide.

Chloroethylphthalimide, $C_8H_4O_2\text{N}\cdot\text{CH}_2\cdot\text{CH}_2\text{Cl}$, is obtained when potassium phthalimide is heated with five times its weight of ethylene dichloride at $180-190^\circ$ for three hours. It crystallises from carbon bisulphide in colourless needles, melts at $79-81^\circ$, and, when heated with concentrated hydrochloric acid at 180° for four hours, yields phthalic acid and chloroethylamine hydrochloride. The latter can be crystallised from amyl alcohol, in which it is less soluble than in the ordinary solvents, and melts at $119-123^\circ$; the picrate and platinochloride of the amine have already been described (*loc. cit.*).

β -Bromopropylphthalimide, $C_8H_4O_2\text{N}\cdot\text{CH}_2\cdot\text{CHBrMe}$, is formed when a mixture of allylphthalimide (1.5 grams) with concentrated hydrobromic acid prepared at 0° (6 c.c.) is allowed to remain in a stop-

pered flask for 24 hours at the ordinary temperature. It separates from methyl alcohol as a silky, felted, crystalline mass, and melts at 105° .

β -Thiocyanopropylphthalimide, $C_8H_4O_2 \cdot N \cdot CH_2 \cdot CHMe \cdot SCN$, is prepared by heating β -bromopropylphthalimide with alcoholic potassium thiocyanate at 170° for four hours. It dissolves in methyl alcohol, cold benzene, and acetic acid, but less readily in light petroleum, and melts at $89-93^{\circ}$.

β -Mercaptopropylphthalimide, $C_8H_4O_2 \cdot N \cdot CH_2 \cdot CHMe \cdot SH$, is obtained when β -bromopropylphthalimide is heated with alcoholic potassium hydrosulphide in a pressure flask for one hour at 100° . After purification by conversion into its mercury salt, it crystallises from alcohol in aggregates melting at 88° . When oxidised by the addition of iodine to its alcoholic solution, it is converted into *β -diphthalimido-propyl bisulphide*, $(C_8H_4O_2 \cdot N \cdot CH_2 \cdot CHMe)_2S_2$, which crystallises in white needles and melts at $159-161^{\circ}$.

The action of aniline on β -bromopropylphthalimide is essentially different from that on the γ -compound (compare Goldenring, Abstr., 1890, 976), and is by no means complete at 150° . When aniline (8 grams) and β -bromopropylphthalimide (9 grams) are heated together on a sand-bath for 20 minutes, a mixture of phthalamil, as chief product, with a relatively small proportion of *β -anilidopropylphthalimide*, $C_8H_4O_2 \cdot N \cdot CH_2 \cdot CHMe \cdot NHPh$, is obtained. The latter crystallises from alcohol in beautiful yellow needles, melts at 93° , and on digestion with concentrated hydrochloric acid at 190° , is decomposed into phthalic acid and a base, probably *β -anilidopropylenediamine*, $NHPh \cdot CH(CH_2 \cdot NH_2)_2$, boiling at $250-260^{\circ}$.

W. P. W.

Azoimide. By E. NOELTING and E. GRANDMOUGIN (*Ber.*, 24, 2546-2547).—Curtius has shown (this vol., p. 56) that triazobenzene or diazobenzeneimide must be regarded as the phenyl salt of azoimide. In view of the stability of such aromatic salts, there appeared little likelihood of eliminating the phenyl group, but it seemed not improbable that the entrance of nitro-groups into the phenyl residue might render the elimination more easy, just as is the case with chlorobenzene.

An experiment with dinitrotriazobenzene has shown that such is really the case. The dinitro-compound was prepared from 1:2:4-dinitraniline by diazotising, converting into the perbromide, and treating this with ammonia; by the action of alcoholic potash, it is converted, apparently very readily, into dinitrophenol and azoimide.

H. G. C.

Orthohydroxyazo-dyes. By J. D. ZIBELL (*Chem. Centr.*, 1891, ii, 56; from *Schweiz. Wochenschr. Pharm.*, 29, 186; compare Abstr., 1884, 742 and 1146).—The author finds that diazobenzene chloride reacts with parahydroxybenzoic acid with separation of the carboxyl group, forming phenylazophenol and phenyldiazophenol. Diazosulphanilic acid reacts similarly, forming sodium phenolazosulphanilate. On the other hand, the azo-compounds obtained by employing ortho- and

meta-hydroxybenzoic acids behaved differently from one another when cotton was dyed with them, only that obtained from orthohydroxybenzoic acid adhering to the fibre. J. W. L.

Thiocarbamides. By H. SALKOWSKI (*Ber.*, 24, 2724—2729).—Symmetrical dibenzylthiocarbamide, $\text{CS}(\text{NH}\cdot\text{CH}_2\text{Ph})_2$, may be readily obtained by heating benzylamine benzylthiocarbamate at 125° until hydrogen sulphide ceases to be evolved; it melts at 148° , not at 114° as stated by Strakosch.

Benzylthiocarbamide, $\text{NH}_2\cdot\text{CS}\cdot\text{NH}\cdot\text{CH}_2\text{Ph}$, is prepared by heating benzylamine thiocyanate at 110° for about 14 hours, and is identical with the product formed by the action of alcoholic ammonia on benzylthiocarbimide; it is soluble in 61 parts of 95 per cent. alcohol, crystallises in colourless, concentric needles, and melts at 164° . Paternò and Spica give the melting point as 101° , and state that the compound is readily soluble in water; they appear, however, to have mistaken benzylamine thiocyanate for benzylthiocarbamide, since the latter is almost insoluble in water, and the former melts, according to the author, at 95° .

Paternò and Spica have made a similar error regarding unsymmetrical dibenzylthiocarbamide, $\text{NH}_2\cdot\text{CS}\cdot\text{N}(\text{CH}_2\text{Ph})_2$, which they obtained by the evaporation of benzylamine hydrochloride and potassium thiocyanate solutions; the author failed to detect the formation of any thiocarbamide in this manner. *Dibenzylamine thiocyanate* is prepared by dissolving dibenzylamine in hot dilute thiocyanic acid; it crystallises in colourless, lustrous plates melting at 164 — 165° . On melting the compound and heating it at 140° for several hours, unsymmetrical dibenzylthiocarbamide is formed; this is insoluble in water, and is deposited from alcohol in small, yellow crystals which melt at 141° .

Contrary to the statement of Clermont, aniline thiocyanate is readily converted into phenylthiocarbamide by dissolving the salt in water, evaporating to dryness, and heating the residue for 2—3 hours on the water-bath. The conversion of methylamine thiocyanate into the corresponding thiocarbamide has not as yet been observed by the author.

Methylthiocarbamide, prepared from methylthiocarbimide and alcoholic ammonia, melts at 119 — 120° instead of below 100° as usually stated in text books.

The observations of O. Hecht regarding symmetrical dimethylthiocarbamide are confirmed.

The above results prove that, in certain cases at all events, the conversion of amine thiocyanates into the corresponding thiocarbamides is independent of the former compounds being in the nascent state. J. B. T.

Derivatives of Bromopiperonal. By A. ORLKER (*Ber.*, 24, 2592—2596).—Bromopiperonal, $\text{CH}_2\text{O}_2\cdot\text{C}_6\text{H}_2\text{Br}\cdot\text{COH}$, is obtained by adding the calculated quantity of bromine to a solution of piperonal in carbon bisulphide in the presence of a small quantity of iodine. The carbon bisulphide is distilled off and the mass boiled with alcohol.

On cooling, it separates in long, white needles, melts at 129–130°, and is identical with the compound obtained by Fittig and Mielk (*Annalen*, 152, 39).

Bromopiperonalphenylhydrazone is obtained in yellow, nacreous scales on adding phenylhydrazine to a solution of the above compound in dilute acetic acid. It melts at 136°, is insoluble in water, and easily soluble in alcohol, ether, and acetone.

Bromopiperonaldoxime is obtained by adding an aqueous solution of hydroxylamine hydrochloride to an alcoholic solution of bromopiperonal. It forms slender, white needles, crystallises from alcohol, melts at 168°, is insoluble in water, but easily soluble in alcohol, ether, and benzene.

Mononitrobromopiperonal, $\text{CH}_2\text{O}_2\cdot\text{C}_6\text{HBr}(\text{NO}_2)\cdot\text{COH}$, is obtained by adding twice the theoretical quantity of nitric acid (1.48) to a cold solution of bromopiperonal in acetic acid. Heat is developed, and the solution must be cooled below 50°, otherwise the action becomes too violent, and the bromopiperonal is decomposed. The mixture is poured into ice-cold water, and the product crystallised from alcohol. It crystallises in beautiful, bright-yellow needles, melts at 90°, and is soluble in all the ordinary solvents except water. When treated with acetone and caustic soda, the mixture becomes red, and an indigo-compound is not formed; hence the author is inclined to believe that the nitro-group is in the meta-position with respect to the aldehyde group. However, dinitrobromopiperonal, in which one nitro-group must be in the ortho-position relatively to the aldehyde group, behaves in a similar way, and does not yield an indigo compound with acetone and alkali. The red coloration is also produced by boiling the compound with alkalis alone, and disappears on the addition of hydrochloric acid.

Dinitrobromopiperonal is obtained by adding bromopiperonal in small portions to well-cooled nitric acid (sp. gr. 1.52), and pouring the solution into ice-cold water. It crystallises from alcohol and acetone in golden-yellow needles, melts at 173°, is insoluble in water, somewhat sparingly soluble in alcohol and ether, easily so in acetone and chloroform, and turns deep yellow on exposure to light.

Bromopiperonylacryl methyl ketone, $\text{CH}_2\text{O}_2\cdot\text{C}_6\text{H}_2\text{Br}\cdot\text{CH}\cdot\text{CH}\cdot\text{COMe}$, is formed, together with dibromodipiperonylacryl methyl ketone, by shaking bromopiperonal (5 grams) with acetone (15 c.c.) and 3 per cent. caustic soda (4–5 c.c.). It is separated by extracting the product with a small quantity of alcohol, in which it is easily soluble; it crystallises in white, lustrous needles, and melts at 152–154°. The *oxime* crystallises from alcohol in slender, white needles, melts at 210° with decomposition, and is sparingly soluble in alcohol and benzene, easily so in acetone and ether. The *phenylhydrazone* crystallises in large, yellow plates, melts at 158°, and is easily soluble in all the usual solvents.

Dibromodipiperonylacryl ketone, $(\text{CH}_2\text{O}_2\cdot\text{C}_6\text{H}_2\text{Br}\cdot\text{CH}\cdot\text{CH})_2\text{CO}$, is sparingly soluble or insoluble in most solvents, crystallises from acetic acid in slender, lemon-yellow needles, and dissolves in concentrated sulphuric acid forming an intense blue solution. Both ketones are sensitive to light.

Bromopiperonyllactyl methyl ketone,

is obtained as an intermediate product in the above condensation when bromopiperonal is dissolved in a large quantity of acetone. It is a yellowish-white, crystalline compound, melts at 110° , is insoluble in cold water, sparingly soluble in hot water, easily so in alcohol, ether, and benzene, and is converted into bromopiperonyllactyl methyl ketone (iii. p. 152°) when boiled with acetic acid. E. C. R.

Isomeric Paranitrobenzaldoximes. By H. GOLDSCHMIDT and C. KJELLIN (*Ber.*, 24, 2547—2556).— α -Paranitrobenzaldoxime was prepared according to the method described by Gabriel and Herzberg (*Abstr.*, 1883, 1104), and exhibited all the properties formerly assigned to it.

Carbanilido- α -paranitrobenzaldoxime, $\text{NHPh}\cdot\text{COO}\cdot\text{N}\cdot\text{CH}\cdot\text{C}_6\text{H}_4\cdot\text{NO}_2$, is obtained by warming equivalent quantities of the oxime and phenyl cyanate dissolved in benzene on the water-bath, and evaporating the solution in a vacuum. It crystallises from alcohol in yellowish-white scales, melts at 157° , and is easily soluble in hot alcohol and benzene, less so in ether, and only very sparingly in light petroleum. When warmed with soda, it is decomposed into the oxime, aniline, and carbonic acid.

α -Paranitrobenzaldoxime methyl ether, $\text{OMe}\cdot\text{N}\cdot\text{CH}\cdot\text{C}_6\text{H}_4\cdot\text{NO}_2$, is obtained by the action of methyl iodide on a mixture of equivalent quantities of the α -oxime and sodium methoxide dissolved in methyl alcohol, and is purified by distillation with steam. It crystallises in white needles, melts at 101° , and is easily soluble in cold alcohol, benzene, light petroleum, chloroform, and ether.

α -Paranitrobenzaldoxime ethyl ether is obtained in a similar way to the methyl ether; the reaction does not, however, take place so easily, and it is necessary to heat the mixture for some time on the water-bath. It crystallises in colourless, tetragonal tablets, melts at 107 — 108° , is easily soluble in the ordinary solvents, and is volatile with steam. When it is heated with alcohol at 200° , paranitrobenzamide, $\text{NO}_2\cdot\text{C}_6\text{H}_4\cdot\text{CO}\cdot\text{NH}_2$, is formed.

β -Paranitrobenzaldoxime is obtained by passing hydrogen chloride into a dry ethereal solution of the α -oxime, and then treating with a solution of soda the hydrochloride of the β -oxime, which separates in small, white needles, and melts at 116° with decomposition. It crystallises from ethyl acetate in small, lustrous tablets, melts at 170 — 176° , and is sparingly soluble in cold alcohol, benzene, and chloroform, more so in hot alcohol, and dissolves in alkalis with a yellowish-red coloration.

Carbanilido- β -paranitrobenzaldoxime is obtained in lemon-yellow needles on adding phenyl cyanate to an ethereal solution of the β -oxime. It melts at 94° with evolution of gas, is easily soluble in benzene, sparingly so in cold alcohol, and is decomposed on warming with alcohol. When warmed with sodium hydroxide, it yields β -paranitrobenzaldoxime, aniline, carbonic acid, paranitrobenzonitrile, and a small quantity of diphenylcarbamide.

Methyl paranitroisobenzaldoxime, $\text{NO}_2\cdot\text{C}_6\text{H}_4\cdot\text{CH} < \begin{smallmatrix} \text{O} \\ \text{NMe} \end{smallmatrix}$, is obtained by the action of methyl iodide on the β -oxime and sodium methoxide dissolved in methyl alcohol. It crystallises from hot alcohol in lemon-yellow needles, melts at 205° , and is sparingly soluble in light petroleum, benzene, ether, and cold alcohol, fairly easily in hot alcohol. When boiled with hydrochloric acid, it yields paranitrobenzaldehyde and methylhydroxylamine, $\text{NHMe}\cdot\text{OH}$. When heated with strong hydriodic acid at 120° , it yields methylamine. A small quantity of the isomeric ether, $\text{NO}_2\cdot\text{C}_6\text{H}_4\cdot\text{CH}\cdot\text{N}\cdot\text{OMe}$, is also formed in the above reaction, and is separated from the mother liquors by steam distillation.

Ethyl paranitroisobenzaldoxime, $\text{NO}_2\cdot\text{C}_6\text{H}_4\cdot\text{CH} < \begin{smallmatrix} \text{O} \\ \text{NEt} \end{smallmatrix}$, is obtained in a similar way to the methyl compound, together with a small quantity of the isomeric ether, $\text{NO}_2\cdot\text{C}_6\text{H}_4\cdot\text{CH}\cdot\text{N}\cdot\text{OEt}$. It crystallises from hot alcohol in lemon-yellow needles, melts at $119\text{--}120^\circ$, is easily soluble in hot alcohol and benzene, sparingly in ether, and almost insoluble in light petroleum. When boiled with hydrochloric acid, it yields paranitrobenzaldehyde and a compound which reduces Fehling's solution, and is probably $\text{NHET}\cdot\text{OH}$.

β -Paranitrobenzaldoxime methyl ether, $\text{NO}_2\cdot\text{C}_6\text{H}_4\cdot\text{CH}\cdot\text{N}\cdot\text{OMe}$, is obtained as follows:—The β -oxime is dissolved in the smallest quantity of soda, and silver nitrate added to the solution. The silver salt thus obtained is collected, suspended in ether, and methyl iodide added. The mixture is shaken from time to time and, after some hours, is filtered; the ethereal filtrate is washed with dilute soda, the ether distilled, and the residue crystallised from petroleum. It crystallises in spear-like needles, melts at $67\text{--}68^\circ$, and is easily soluble in the ordinary solvents.

β -Paranitrobenzaldoxime ethyl ether, $\text{NO}_2\cdot\text{C}_6\text{H}_4\cdot\text{CH}\cdot\text{N}\cdot\text{OEt}$, is obtained in a similar way to the methyl compound; it crystallises from petroleum in colourless needles, melts at $70\text{--}71^\circ$, and is easily soluble in the ordinary organic solvents. When heated with alcohol at $190\text{--}200^\circ$, a product melting at 145° is obtained; on further heating, paranitrobenzamide is obtained.

The last two β -compounds are easily converted into α -compounds by dissolving them in carbon bisulphide containing a little iodine, and heating the mixture on a water-bath.

A determination of the molecular weights of the above compounds gave results agreeing with the formula $\text{NO}_2\cdot\text{C}_6\text{H}_4\cdot\text{CH}\cdot\text{NOR}$, both for the α - and β -compounds.

E. C. R.

Additive Compounds of Alkylisaldoximes. By H. GOLDSCHMIDT and C. KJELLIN (*Ber.*, 24, 2808—2817).—The compound

$\text{NO}_2\cdot\text{C}_6\text{H}_4\cdot\text{CH} < \begin{smallmatrix} \text{O} \\ \text{NMe, NaI} \end{smallmatrix}$ separates when a methyl alcoholic solution of metanitroisobenzaldoxime is mixed with sodium ethoxide and methyl iodide in molecular proportion, and the mixture concentrated, whilst methylmetanitroisobenzaldoxime, $\text{NO}_2\cdot\text{C}_6\text{H}_4\cdot\text{CH}\cdot\text{N}\cdot\text{OMe}$, melting at 72° (compare Abstr., 1890, 1262) remains in the mother

liquor; the additive compound is likewise obtained when the above mixture is allowed to remain for a time, filtered from sodium iodide, evaporated to dryness, and the methylmetanitroisobenzaldoxime (m. p. 72°) extracted with ether from the residue; also when its components are heated together in a sealed tube at 100° . It forms large, yellow plates, melts at 180 – 185° , and is readily soluble in alcohol, but when dissolved in hot water, it is decomposed into methylmetanitroisobenzaldoxime (m. p. 117° ; *loc. cit.*); benzene and ether also decompose it. It is unaltered when heated in a current of dry air at 160° , whilst at 190° methylamine passes over.

Ethylmetanitroisobenzaldoxime, $\text{NO}_2\cdot\text{C}_6\text{H}_4\cdot\text{CH} < \begin{smallmatrix} \text{O} \\ \text{NEt} \end{smallmatrix}$, is obtained from metanitroisobenzaldoxime, ethyl iodide, and sodium ethoxide; it crystallises from boiling water in yellowish needles, melts at 97° , and is only slightly soluble in cold water, sparingly in ether and light petroleum, readily in alcohol and hot benzene; the formation of a compound with sodium iodide was not observed here.

The two stereoisomeric *ethylmetanitrobenzaldoximes*, $\text{NO}_2\cdot\text{C}_6\text{H}_4\cdot\text{CH} < \begin{smallmatrix} \text{O} \\ \text{EtON} \end{smallmatrix}$ and $\text{NO}_2\cdot\text{C}_6\text{H}_4\cdot\text{CH} < \begin{smallmatrix} \text{O} \\ \text{N-OEt} \end{smallmatrix}$, were also prepared; they are both oils.

The compound $\text{CHPh} < \begin{smallmatrix} \text{O} \\ \text{NMe, NaI} \end{smallmatrix}$ is produced from isobenzaldoxime, sodium ethoxide, and methyl iodide in methyl alcoholic solution; also by evaporating mixed aqueous solutions of methylisobenzaldoxime and sodium iodide in molecular proportion; it melts at 69 – 72° , dissolves readily in water and alcohol, is slowly decomposed by benzene and ether, and gives a brown precipitate which readily undergoes decomposition when treated with a concentrated aqueous solution of copper acetate. When an aqueous solution, to which common salt has been added, is extracted with ether, methylisobenzaldoxime, $\text{CHPh} < \begin{smallmatrix} \text{O} \\ \text{NMe} \end{smallmatrix}$, is obtained from the ethereal solution; on adding light petroleum to its solution in a little benzene, it separates in colourless plates; it melts at 82° , and is readily soluble in water, alcohol, and benzene, somewhat less so in ether; it decomposes when heated with dilute hydrochloric acid, and in addition to the above described sodium iodide compound, it appears to form a similar derivative with calcium chloride. Unlike isobenzaldoxime, it is not volatile, and as methyl derivatives are invariably more readily volatile than their parent substances, it would seem that isobenzaldoxime has not the constitution $\text{CHPh} < \begin{smallmatrix} \text{O} \\ \text{NH} \end{smallmatrix}$ previously ascribed to it.

Ethylisobenzaldoxime, $\text{CHPh} < \begin{smallmatrix} \text{O} \\ \text{NEt} \end{smallmatrix}$, likewise yields a compound with sodium iodide; this melts at 67 – 70° .

When methylisobenzaldoxime (m. p. 82°) and phenyl cyanate are dissolved in benzene in molecular proportion, and the solution, after remaining for 24 hours, evaporated, the additive compound, $\text{C}_{15}\text{H}_{14}\text{N}_2\text{O}_2$,

which crystallises from alcohol in white needles and melts at 119° , is obtained; when heated with concentrated hydrochloric acid in a sealed tube at 100° , carbonic anhydride, aniline, ammonia, and benzaldehyde are formed. The compound $C_{16}H_{16}N_3O_2$, melting at $116-117^{\circ}$, is prepared from ethylisobenzaldoxime and phenyl cyanate; when heated with concentrated hydrochloric acid at 100° , it yields the same decomposition products as the methyl derivative. In like manner the compound $C_{16}H_{16}N_3O_2$, melting at 148° , is formed from ethylmetanitroisobenzaldoxime (m. p. 67°) and phenyl cyanate: whilst the compound $C_{21}H_{17}N_3O_4$, melting at $158-159^{\circ}$, is produced from benzylmetanitrobenzaldoxime and phenyl cyanate.

A. R. L.

Homologues of Benzhydramine. By H. GOLDSCHMIDT and H. STÖCKER (*Ber.*, 24, 2797-2808).—*Paratolhydramine*,

is prepared from paratolylketoxime (Goldschmidt, *Abstr.*, 1890, 1412) as follows:—The ketoxime (5 grams) is treated in alcoholic solution with 2.5 per cent. sodium amalgam (105 grams) and acetic acid at 60° (compare *Abstr.*, 1887, 249). The product is poured into water, sodium hydroxide added, and the mixture extracted with ether; on distilling the ethereal solution, a white, crystalline mass is left, from which paratolhydramine is extracted by boiling with light petroleum, whilst paratoluic paratoluide (Goldschmidt, *loc. cit.*) remains undissolved. It separates from light petroleum in transparent tablets, melts at 93° , and is readily soluble in ether and alcohol. The *hydrochloride*, formed by passing hydrogen chloride into a solution of the base in light petroleum, separates from water in white needles, and melts at 235° ; whilst the *acetyl derivative*, $C_{16}H_{15} \cdot NHAc$, obtained by boiling the base with acetic anhydride, crystallises from alcohol in delicate, white needles, and melts at 159° . When a solution of potassium cyanate is added to a hot aqueous solution of the hydrochloride, *paratolhydrylicarbamide*, $CH(O_2H_4Me)_2 \cdot NH \cdot CO \cdot NH_2$, is produced; it separates from dilute alcohol in small, white needles, and melts at 152° .

Parahomobenzhydramine, $C_6H_4Me \cdot CHPh \cdot NH_2$, is obtained, together with paratoluic anilide, by reducing crude paratolylphenylketoxime (Hantzsch, *Abstr.*, 1890, 1273) as above, employing sodium amalgam (110 grams) and the ketoxime (5 grams). The product is thrown into water, acidified with hydrochloric acid, and extracted with ether to remove the anilide; it is then rendered alkaline and again extracted with ether; on distilling the second ethereal solution, parahomobenzhydramine is obtained as an oil having a faint basic odour and boiling at 296° (723 mm.); it is sparingly soluble in water, cannot be solidified, and absorbs carbonic anhydride from the air. The *hydrochloride* crystallises from boiling water in quadratic prisms, and melts at 252° ; the *platinochloride*, $(C_{14}H_{15}N)_2 \cdot H_2PtCl_6 + 2H_2O$, is a bright yellow, crystalline precipitate which dissolves sparingly in water, but more readily in alcohol, and melts at 119° ; whilst the *acetyl derivative*, $C_{14}H_{13} \cdot NHAc$, crystallises from alcohol in white needles, and melts at 131° . When a solution of potassium

cyanate is added to a hot aqueous solution of the hydrochloride, *parahomobenzhydrylcarbamide*, $C_6H_4Me \cdot CHPh \cdot NH \cdot CO \cdot NH_2$, separates; it crystallises from dilute alcohol in white needles, and melts at 158° . *Parahomobenzhydrylaminethiocarbamide*, $C_6H_4Me \cdot CHPh \cdot NH \cdot CS \cdot NH_2$, is obtained by treating an aqueous solution of the hydrochloride with the theoretical quantity of potassium thiocyanate, evaporating to dryness, extracting with absolute alcohol, and again evaporating; the oil thus obtained soon solidifies to reddish needles, which are rendered colourless by washing with ether; it melts at $100-101^\circ$. *Parahomobenzhydrylphenylcarbamide*, $C_6H_4Me \cdot CHPh \cdot NH \cdot CO \cdot NHPh$, is formed when phenyl cyanate is added to an ethereal solution of the base; it separates from boiling alcohol in small, white needles, and melts at 206° . *Parahomobenzhydrylamine* contains an asymmetric carbon atom, but, as might be anticipated, since it is a synthetical product, is optically inactive. The authors were not, however, successful in resolving it into two optically active isomerides by crystallisation of either the monodextrotartrate or of the normal salt; they also find that the same base is formed by reducing pure α -paratolylphenylketoxime (Hantzsch, *loc. cit.*) instead of the crude ketoxime, together also with paratoluic anilide. The *monodextrotartrate*, $C_{14}H_{15}N, C_4H_4O_6$, forms small, white needles, and melts at 157° ; whilst the normal *dextrotartrate*, $(C_{14}H_{15}N)_2, C_4H_4O_6$, which is only produced when concentrated solutions of the acid and base are mixed in the requisite proportion, separates in white, microscopic needles, and melts at $72-73^\circ$.

Orthotolyl phenyl ketone, $C_6H_4Me \cdot COPh$, prepared from orthotoluic chloride by the method described by Elbs (Abstr., 1886, 461), for the preparation of aromatic ketones, boils at 295° (722 mm.); compare Ador and Rilliet (*Ber.*, 12, 2301). The *oxime* forms white needles, and melts at $95-98^\circ$; it is probably a mixture of two stereochemical isomerides.

Orthohomobenzhydrylamine, $C_6H_4Me \cdot CHPh \cdot NH_2$, is formed, together with orthotoluic anilide, by reducing orthotolylphenylketoxime with sodium amalgam; the two products are isolated in the same manner as those of the para-series (see above). The new base is a colourless oil which boils at 299° (721 mm.), absorbs carbonic anhydride from the air, and is somewhat soluble in water. The *hydrochloride* begins to darken at 220° , melts at 240° , and is readily soluble in water; whilst the *acetyl* derivative crystallises from alcohol in small, white prisms, and melts at 124° .

Metatolyl phenyl ketone, prepared from metatoluic chloride, boils at $311-313^\circ$ (723 mm.); compare Ador and Rilliet (*loc. cit.*); the *oxime* melts at $100-101^\circ$, and is perhaps a mixture of two stereochemical isomerides.

Metahomobenzhydrylamine, $C_6H_4Me \cdot CHPh \cdot NH_2$, is a colourless oil closely resembling its isomerides; it boils at 299° (724 mm.); the *hydrochloride* forms delicate, white needles, commences to darken at 220° , melts completely at 243° , and is fairly soluble in water; whilst the *acetyl derivative* crystallises from alcohol in colourless needles, and melts at 97° .

A. R. L.

Conversion of Gallic Acid and Tannin into Benzoic Acid. By C. E. GUIGNET (*Compt. rend.*, 113, 200—201).—When a warm solution of gallic acid is added to a warm mixture of zinc powder and ammonia solution, the gallic acid is completely converted into benzoic acid after heating for some hours at 60°. A similar result is obtained by heating gallic acid with zinc and dilute sulphuric acid, except that in this case the benzoic acid remains undissolved.

Under similar conditions, tannin is first converted into gallic acid, and finally into benzoic acid. C. H. B.

Hydrogenation of Benzoic Acid. By O. ASCHAN (*Ber.*, 24, 2617—2622; compare this vol., p. 1053).—*Hexahydrobenzoic acid* is obtained, together with benzoic acid, when the product of the action of hydrogen bromide on tetrahydrobenzoic acid (*loc. cit.*) is reduced with sodium amalgam. In the pure and anhydrous form, it melts at 28°, and boils at 224° under 725 mm. pressure. The *amide*, $C_6H_{11}CONH_2$, crystallises from water in large, flat prisms melting at 184°, and the *methyl salt* boils at 175—176° under 719 mm. pressure, and has a density of 1.014 at 0°/0°, and 0.9927 at 20°/20°. The acid is not affected by heating with concentrated hydrochloric acid at 170—250°, and does not seem to be identical with the author's hexanaphthenecarboxylic acid (*Abstr.*, 1890, 737).

α -Bromhexahydrobenzoic acid, $C_6H_{10}BrCOOH$, is prepared by heating the mixture of phosphorus oxychloride and the acid chloride, produced by the action of phosphorus pentachloride on hexahydrobenzoic acid, with the calculated quantity of bromine at 100—120°, and extracting the product with formic acid (sp. gr. = 1.2). It crystallises from formic acid in large, silvery scales or flat prisms, melts at 63°, has an odour of iodoform, and is unstable in the presence of boiling water and alkalis.

Δ^1 -Tetrahydrobenzoic acid is obtained when *α -bromhexahydrobenzoic acid* is treated with alcoholic potash at the ordinary temperature and the product is distilled with steam. It is a colourless oil which boils at 235—236° under 718 mm. pressure, and, when cooled below 0°, solidifies to a crystalline mass melting at about 8°. Bromination takes place only slowly and incompletely when the acid is treated with bromine, and leads to the production of the two stereometric dibromides, which could not be satisfactorily separated, although they differ in solubility and crystalline form, the less soluble substance crystallising in prisms, and the more soluble in lamelliform rhombohedra. If, however, the mixture of acid chloride and phosphorus oxychloride formed by the action of phosphorus pentachloride on the acid is treated with the calculated quantity of bromine, and the brominated acid chloride converted into the acid by prolonged boiling with excess of formic acid (sp. gr. = 1.2), the less soluble dibromide of *Δ^1 -tetrahydrobenzoic acid* is the sole product. This crystallises from concentrated formic acid, dilute acetic acid, or a mixture of benzene and light petroleum in small, prismatic forms, melts at 142°, and regenerates the tetrahydro-acid when boiled with alkalis or alkaline carbonates, or if treated in the cold with alcoholic potash.

Δ^1 -Tetrahydrobenzamide crystallises from ether in octahedra, and melts at 127—128°.

The tetrahydrobenzoic acid obtained by the reduction of benzoic acid with sodium amalgam (*loc. cit.*), is most probably the Δ^2 -acid, since, on the one hand, it yields the Δ^1 -acid by boiling with strong, aqueous potash, and, on the other, its methyl salt is converted into methyl benzoate by atmospheric oxygen, reactions which, according to v. Baeyer's experience, are characteristic of hydrophthalic acids containing a "double bond" in the Δ^2 -position. The action of bromine on this acid leads to the formation of only one dibromide, further examination having shown that the supposed isomeride is nothing but benzoic acid, which is almost always present in small quantity in the crude tetrahydro-acid. The pure dibromide crystallises from dilute acetic acid in lustrous, colourless scales, and melts at 166°, not at 163°. Δ^2 -Tetrahydrobenzamide forms white, nacreous scales or prisms, melts at 144°, and is more soluble in water and ether than the amide of the Δ^1 -acid.

A dihydrobenzoic acid, possibly the $\Delta^{1,2}$ -acid, is formed by the action of concentrated alcoholic potash on the dibromide of the Δ^1 -tetrahydro-acid at the ordinary temperature. It crystallises from its concentrated aqueous solution, by slow evaporation in the cold, in large, hard prisms which melt at 73°.

W. P. W.

β -Dichlorhydrin Metahydroxybenzoate. By C. GÖTTIG (*Ber.*, 24, 2741—2743; compare this vol., p. 707).—Metahydroxybenzoic acid is dissolved in 10 parts of glycerol, the solution heated at 85°, and treated with hydrogen chloride for five hours; two compounds are formed, and may be separated by solution in hot water. The one is amorphous, and has not been further investigated; the second consists of β -dichlorhydrin metahydroxybenzoate, $\text{OH}\cdot\text{C}_6\text{H}_4\cdot\text{CO}\cdot\text{OC}_2\text{H}_4\text{Cl}$, and crystallises in long, slender needles which melt at about 90°. The constitution of the compound is proved by the fact that on hydrolysis with soda or potash, metahydroxybenzoic acid and epichlorhydrin are formed as the sole products. If the etherification of the metahydroxybenzoic acid is conducted at temperatures above 85°, the yield of the amorphous compound is proportionately increased.

J. B. T.

Optically Active Phenylbromolactic Acids and Phenoxyacrylic Acids. By E. ERLENMEYER, Jun. (*Ber.*, 24, 2830—2831).—Optically inactive phenylbromolactic acid can be easily separated into its optically active constituents by conversion into the cinchonine salt and crystallisation from alcohol. The salt of the dextrorotatory acid crystallises almost completely from the solution when a certain concentration is reached, and the remainder can be separated by the addition of ether. The salt of the levorotatory acid is left as a viscid mass after evaporation of the alcoholic mother liquor, and can be obtained in the solid form by repeated treatment with pure ether. The optically active acids, obtained from the salts by treatment with dilute hydrochloric acid and extraction with ether, closely resemble the optically inactive acid in properties; the melting points, however, are not identical.

The sodium salts of the optically active phenoxyacrylic acids are formed when the optically active phenylbromolactic acids are treated with aqueous caustic soda. The aqueous solutions of these salts exhibit a greater rotatory power than the solutions of the phenylbromolactic acids, and, moreover, the salt derived from dextrorotatory phenylbromolactic acid rotates to the left, whilst that from the levorotatory acid rotates to the right. On treatment with sulphuric acid, both salts are converted into phenylethylaldehyde. A detailed account of the physical properties of these optically active isomerides is reserved for a later communication.

W. P. W.

Diiodocinnamic Acid. By C. LIEBERMANN and H. SACHSE (*Ber.*, 24, 2588—2589).—*Diiodocinnamic acid*, $\text{C}_6\text{H}_4\text{I}_2\text{COOH}$, is obtained by allowing a solution of molecular proportions of phenylpropionic acid and iodine in carbon bisulphide to remain exposed to sunlight in a stoppered bottle. The iodine is very slowly absorbed, and is still visible after a month. The mixture deposits beautiful leaflets having a silvery lustre. It is purified by dissolving in alcohol and precipitating with water, and melts at 171° . The *sodium* salt is obtained in beautiful needles by dissolving the acid in dilute sodium carbonate, and then adding excess of the reagent. The *barium* salt is soluble; the *lead* salt forms a white precipitate. With sodium amalgam, it yields hydrocinnamic acid.

Methyl diiodocinnamate is obtained from methyl phenylpropionate in a similar way. It is easily soluble in alcohol, and is precipitated, on the addition of water, in scales of silvery lustre, and melts at 77° .

E. C. R.

Nitration of Cinnamic Acid and Phenylmethacrylic Acid in the Side Chain. By H. ERDMANN (*Ber.*, 24, 2771—2775).—The author has previously obtained phenylnitroethylene in small quantity by the action of red fuming nitric acid on phenylisocrotonic acid (*Abstr.*, 1884, 906). Phenylnitroethylene is also formed in very small quantity when cinnamic acid is stirred into warm, red fuming nitric acid; in larger quantity when an ethereal solution of the acid, cooled in a bath of ice and salt, is saturated with nitrous gas obtained by the action of arsenious anhydride on nitric acid, and to the extent of 15 per cent. of the theoretical, when a mixture of the acid (20 grams) with 10 per cent. aqueous sodium nitrite (100 c.c.) is distilled with steam.

Phenylnitropropylene is obtained when a cold, ethereal solution of phenylmethacrylic acid is treated with nitrous gas, and a volatile product of aromatic odour is formed in very small quantity from phenylangelic acid under like conditions.

Two stereometric forms of phenylnitroethylene are conceivable, and the author is of opinion that the formula $\begin{array}{c} \text{Ph}\cdot\text{C}\cdot\text{H} \\ | \\ \text{H}\cdot\text{C}\cdot\text{NO}_2 \end{array}$ is the more prob-

able for the compound produced in the above reactions. This view seems to derive some confirmation from the fact that all attempts to reduce orthonitrophenylnitroethylene to cinnoline have been fruitless.

W. P. W.

Condensation of Allocinnamic Acid with Phenols. By C. LIEBERMANN and A. HARTMANN (*Ber.* 24, 2582—2587).—The following method of condensation is employed:—Finely powdered allocinnamic acid (10 grams) is dissolved in phenol (10 grams) and acetic acid (5 c.c.); the mixture cooled and mixed with strong sulphuric acid (10 c.c.) diluted with acetic acid (5 c.c.). After remaining four days, the viscid mass is poured into water, and extracted with ether. The ethereal solution is shaken with water to get rid of acetic acid, and then extracted with soda, and finally the ether is distilled off. An oil is thus obtained which has a phenolic odour, and gradually solidifies; it is then spread on porous plates to remove adhering oil. If a crystal of the substance thus obtained be added to the oil from later experiments, it at once solidifies. The substance is phenylhydrocoumarin. The soda solution contains hydroxydiphenylpropionic acid.

Hydroxydiphenylpropionic acid, $C_{15}H_{14}O_3$, is obtained from the above soda solution by acidifying and extracting with ether. It is very soluble in alcohol, crystallises from benzene in plates, and melts at 151° . The ammonium salt loses ammonia on evaporation of its solution. Lead acetate and silver nitrate cause white precipitates when added to solutions of the ammonium salt. The calcium and barium salts are very soluble. The author puts forward two formulæ for the compound,

of which he considers the former to be the more probable. The acid is not converted into phenylhydrocoumarin when heated at 160° .

Phenylhydrocoumarin, $C_{15}H_{12}O_2$, an indifferent compound, is insoluble in soda, dissolves easily in alcohol, and on the addition of water is obtained in beautiful, colourless needles; it crystallises from light petroleum in rosettes of needles, melts at 82° , and distils at 237° under a pressure of 30 mm., for the most part without decomposition. When boiled with alkali, it dissolves, and on adding an acid to the solution a white compound is precipitated, which is only partly soluble in soda, as it rapidly changes into phenylhydrocoumarin.

Phenylhydroxyhydrocoumarin, $C_{15}H_{12}O_3$, is obtained by condensation of allocinnamic acid with resorcinol by the method described above. It is easily soluble in most solvents, almost insoluble in light petroleum, and quite so in water, gives a yellow solution with soda or ammonia, and a yellow lead salt on the addition of lead acetate to the ammoniacal solution.

The condensation of cinnamic acid with phenol does not give good results under the above conditions. The condensation was effected by heating cinnamic acid (5 grams), phenol (5 grams), sulphuric acid (7 grams), and acetic acid (7 grams) on the water-bath for an hour. From the product, phenylhydrocoumarin was obtained, identical with that obtained from allocinnamic acid. The condensation takes place very slowly in the cold.

Amidobenzoic Derivatives of Ethyl Acetoacetate. By G. PELLIZZARI (*Gazzetta*, 21, 340—345).—It has been shown by Knorr (*Abstr.*, 1887, 159) and Conrad and Limpach (*Abstr.*, 1887, 679;

Ber., 22, 78) that aromatic amines generally react in two ways with ethyl acetoacetate according to the conditions of the experiment. The author investigates these reactions in the case of amidobenzoic acid.

Ethyl hydrogen ac-mctacrotonamidobenzoate, $C_{13}H_{15}NO_4$, is obtained by boiling a solution of metamidobenzoic acid (10 grams) and ethyl acetoacetate (10 grams) in 96 per cent. alcohol (20 grams) for one hour; on cooling, the whole solidifies to a crystalline mass, which, after recrystallisation from alcohol, is obtained in beautiful, colourless prisms melting at 137° . It is very soluble in alcohol and ether, and on prolonged heating in aqueous solution breaks up into its constituents, the yield of amidobenzoic acid being quantitative. It has probably the constitution $COOEt \cdot CH : CMe \cdot NH \cdot C_6H_4 \cdot COOH$. Attempts to eliminate alcohol and obtain a quinoline derivative, as may be done in analogous cases, did not succeed.

ac-Acetylacetometamidobenzoic acid, $COMe \cdot CH_2 \cdot CO \cdot NH \cdot C_6H_4 \cdot COOH$, is obtained by directly heating a mixture of equivalent proportions of metamidobenzoic acid and ethyl acetoacetate; the semi-fluid mass is extracted with ether to remove the unaltered constituents, and recrystallised from alcohol; it is then obtained in colourless crystals very soluble in hot alcohol and acetic acid, moderately so in water, and melting with decomposition at $172-173^\circ$. The *silver salt* is a white powder. On endeavouring to prepare a quinoline derivative by heating the acid with concentrated sulphuric acid, nothing but amidobenzoic acid sulphate was obtained. *Acetylacetorthamidobenzoic acid* is obtained in a manner quite analogous to the meta-acid as white needles melting with decomposition at 160° . It is moderately soluble in hot alcohol and water, less so in benzene, and only sparingly in ether.

W. J. P.

Action of Phthalic Chloride on Phenols. By R. MEYER (*Ber.*, 24, 2600; see also this vol., p. 1029).—Ethereal salts of phthalic acid are usually formed by the action of phthalic chloride on phenols, and not phthaleins or their anhydrides; for instance, phenyl phthalate has been prepared by this method. Paracresol and pseudocumenol also yield the corresponding ethereal salts, which are very well crystallised compounds. β -Naphthol and phthalic chloride yield, as the chief product, naphthyl phthalate, together with a compound which melts above 200° , dissolves in sulphuric acid with an intense reddish-yellow fluorescence, and is evidently the anhydride of β -naphtholphthalein. The author reserves a full description of the compounds for a future communication.

E. C. R.

Relationship between Ethyl Succinosuccinate and Phloroglucinol. By A. v. BAEYER (*Ber.*, 24, 2687—2690).—The author and Kochendörfer have previously shown that phloroglucinol combines with 2 mols. of phenylhydrazine yielding a dihydrazine derivative (*Abstr.*, 1889, 1162); the formation of this compound may be explained by assuming that the triketohexamethylenedihydrazono first produced undergoes intramolecular change.

Ethyl succinosuccinate shows a behaviour similar to that exhibited

by phloroglucinol, and with phenylhydrazine gives a hydrazine derivative of dihydroterephthalic acid (compare following abstracts). Now, since diketohexamethylene, the parent substance of succinosuccinic acid, behaves like a true diketone (compare Baeyer and Noyes, *Abstr.*, 1889, 1147), its conversion into a phenol, analogous to phloroglucinol, in the reaction just referred to, must be due to the presence of the carboxyethyl groups. The fact that a hydroxy-derivative of dihydrobenzene, which shows all the properties of a phenol, can be obtained by simple substitution in the nucleus is of fundamental importance with regard to the benzene theory; for, if in dihydrobenzene the double binding which, on the introduction of a hydroxyl-group, is converted into a single binding with formation of a ketone (in accordance with Erlenmeyer's rule), attains the character of the double binding in phloroglucinol simply owing to the presence of a carboxyethyl group, there is no reason to deny the probability of other substitutions or other changes in the molecule giving a stability to the double binding similar to that observed in the case of benzene derivatives. The objection might be raised that the stability of the double binding in ethyl succinosuccinate is due to the fact that the substituting groups are in the para-position to one another; such a view is negatived by the observation of Baeyer and Tutein (*Abstr.*, 1889, 1180) that hydroxytetrahydroterephthalic acid behaves just like succinosuccinic acid.

F. S. K.

Phenylhydrazine Derivatives of Ethyl Succinosuccinate.

By A. v. BAEYER, R. JAY, and L. JACKSON (*Ber.*, 24, 2690—2691).—Ethyl parabenzenedihydrazo- $\Delta^{2,5}$ -dihydroterephthalate, $C_{24}H_{28}N_4O_4$, is formed, together with the isomeric $\Delta^{1,4}$ -compound, when finely divided ethyl succinosuccinate (5 grams) is warmed with phenylhydrazine (4.2 grams) and alcohol (15 grams) until solution is complete; after keeping the mixture for 3 to 4 days, the crystals are separated by filtration, and extracted with boiling alcohol, from which, on cooling, the $\Delta^{2,5}$ -derivative is deposited in colourless needles. It turns yellow at 135—140°, sinters together at 145°, melts at 165° with decomposition, and is soluble in 15 parts of boiling alcohol; it is unstable towards acids and alkalis, and dissolves in cold, concentrated mineral acids, and in acetic acid and formic acid yielding red solutions; its solution in propionic acid has a reddish hue, but it dissolves in valeric acid yielding a colourless solution which, on heating, suddenly turns yellow, crystals of the $\Delta^{1,4}$ -compound being deposited. When heated alone or in alcoholic solution, it is converted into the isomeride described below.

Ethyl parabenzenedihydrazo- $\Delta^{1,4}$ -dihydroterephthalate (Knorr and Bülow's ethyl diphenylizinsuccinosuccinate), $C_{24}H_{28}N_4O_4$, prepared as described above, is very sparingly soluble in all ordinary solvents and can be easily purified by extraction with boiling alcohol; it is a yellow, microscopic, crystalline powder, melts at 208°, and behaves like the $\Delta^{2,5}$ -derivative on treatment with acids and alkalis.

F. S. K.

Constitution of the Phenylhydrazine Derivatives of Ethyl Succinosuccinate. By A. v. BAEYER and G. v. BRÜNING (*Ber.*, 24,

2692—2699).—*Ethyl benzenebiazo- $\Delta^{1:3}$ -dihydroterephthalate*, $C_{24}H_{24}N_4O_4$, can be obtained in yellow needles by gradually adding a hot, saturated alcoholic solution of normal copper acetate (7 grams), acidified with a little acetic acid, to a boiling alcoholic solution of the $\Delta^{2:5}$ -hydrazo-compound described in the preceding abstract, and then dropping the filtered solution on to ice; it melts at 155° , is readily soluble in alcohol and other ordinary solvents, and dissolves in concentrated hydrochloric acid and concentrated sulphuric acid, yielding red solutions. It is much more stable than the $\Delta^{2:5}$ -hydrazo-compound; on reduction, it is converted into the $\Delta^{1:4}$ -hydrazo-derivative, intramolecular change taking place.

Ethyl benzenebiazoterephthalate, $C_{24}H_{22}N_4O_4$, is formed, with liberation of hydrogen bromide, when bromine is added to an alcoholic solution of the preceding compound; it crystallises from alcohol in long, lustrous, orange-red needles and melts at 126° . It resembles the dihydrazo-derivative in appearance, but is more readily soluble in alcohol and much more stable. The corresponding acid, $C_{20}H_{14}N_4O_4$, prepared by hydrolysing the ethyl salt with boiling concentrated potash, crystallises from a mixture of glacial acetic acid, water, and alcohol in orange-red needles, melts above 250° , and is readily soluble in alcohol and other organic solvents, but insoluble in water. The silver salt, $C_{20}H_{12}N_4O_4Ag_2$, is a dark-red, crystalline powder.

Ethyl benzenebiazo- $\Delta^{1:4}$ -dihydroterephthalate, $C_{24}H_{24}N_4O_4$, is formed when the corresponding dihydrazo-compound (compare preceding abstract) is oxidised with copper acetate as described above, but the solution must be boiled for a much longer time, owing to the insolubility of the hydrazo-compound; the $\Delta^{1:4}$ -bIAzo-derivative is also formed, together with varying quantities of the corresponding $\Delta^{2:5}$ -compound, from which it is produced by intramolecular change, when the $\Delta^{2:5}$ -dihydrazo-derivative is oxidised with copper acetate in presence of water. It crystallises from alcohol in light-yellow needles, melts at 180° , and is more sparingly soluble than its isomeride; it dissolves in hydrochloric acid with a red coloration, and, on reduction, it is converted into the $\Delta^{1:4}$ -dihydrazo-compound. When treated with bromine in chloroform solution, the colour of the mixture changes from brown to red and crystals of a bromo-derivative, melting at 253 — 254° , are deposited; if, however, a solution of the azo-compound in concentrated sulphuric acid is treated with bromine, ethyl benzenebiazoterephthalate, identical with the compound described above, is obtained.

The isomerism of the two compounds obtained by the action of phenylhydrazine on ethyl succinosuccinate is caused by a difference in the constitution of the dihydroterephthalic acids of which they are derivatives. It has been previously shown that, on careful reduction, terephthalic acid is first converted into the readily soluble $\Delta^{2:5}$ -dihydro-acid, which, when boiled with soda, is transformed into the sparingly soluble, stable $\Delta^{1:4}$ -dihydro-derivative; in an exactly analogous manner, ethyl succinosuccinate gives, in the first place, the colourless, unstable hydrazo-derivative, which is readily converted into the yellow, stable, insoluble isomeride.

Now, in accordance with theory, three isomeric benzenebihydrazo-

dihydroterephthalic acids, namely the Δ^2 -, Δ^1 -, and Δ^1 -compounds, differing from one another only as regards the position of the double linking, can be derived from a hydrazone of the constitution $\text{COOEt} \cdot \text{CH} < \text{C}(\text{N}_2\text{HPh}) \cdot \text{CH}_2 > \text{CH} \cdot \text{COOEt}$, the hypothetical primary product of the action of phenylhydrazine on ethyl succinosuccinate; since the Δ^2 -compound may, theoretically, exist in two forms, the maleinoid and the fumaroid, a fourth isomeride is also capable of existence. The only two isomerides which have yet been obtained show the same relation to one another as that existing between the fumaroid Δ^2 - and the Δ^1 -dihydroterephthalic acids; it may be assumed, therefore, at any rate provisionally, that they have the constitutions assigned to them above.

This investigation affords an interesting contribution to the question of the relation between colour and constitution; the above facts show that, by a slight change in the position of the double linking, a yellow compound may become colourless, and *vice versa*.

F. S. K.

Sulphonation of Parachloronitrobenzene and Parachloraniline. By A. CLAUS and C. MANN (*Annalen*, 265, 87—95).—*Chloronitrobenzenesulphonic acid* [$\text{Cl} : \text{SO}_3\text{H} : \text{NO}_2 = 1 : 2 : 4$] is best prepared by adding parachloronitrobenzene to 10—12 per cent. anhydrosulphuric acid (6 parts) and then heating the mixture at 120—130° until it is completely soluble in dilute alkali; no other sulphonic acid is formed even when the conditions of the experiment are altered. It separates from water in well-defined, almost colourless, asymmetric crystals, $a : b : c = 0.8584 : 1 : 0.8520$, containing 2 mols. H_2O , both of which are expelled at 110°; it is readily soluble in water, but only very sparingly in alcohol. The *ammonium* salt, with $1\text{H}_2\text{O}$, *sodium* salt, with $1\text{H}_2\text{O}$, and the *potassium* salt (anhydrous) are crystalline compounds, readily soluble in water, but only sparingly in alcohol. The *barium* salt (anhydrous), *calcium* salt, with $8\text{H}_2\text{O}$, *copper* salt, with $5\text{H}_2\text{O}$, and *lead* salt, with $7\text{H}_2\text{O}$, are readily soluble in hot water and crystallise well. The *chloride*, $\text{N}(\text{O}_2)\text{C}_6\text{H}_4\text{Cl} \cdot \text{SO}_3\text{Cl}$, crystallises from ether in yellowish prisms melting at 89—90° (uncorr.). The *amide*, $\text{NO}_2\text{C}_6\text{H}_4\text{Cl} \cdot \text{SO}_3 \cdot \text{NH}_2$, crystallises in colourless, lustrous needles and prisms, melts at 185—186° (uncorr.), and is readily soluble in ether, chloroform, alcohol, and hot water.

Chloramidobenzenesulphonic acid [$\text{Cl} : \text{SO}_3\text{H} : \text{NH}_2 = 1 : 2 : 4$], prepared by reducing the preceding compound with tin and boiling dilute hydrochloric acid, crystallises from hot water in colourless, prismatic needles. The *barium* salt, with $6\text{H}_2\text{O}$, is almost insoluble in alcohol, but very readily soluble in hot water, from which it separates in small needles. The *stannochloride* crystallises in large, lustrous prisms.

Two isomeric sulphonic acids are formed when parachloraniline sulphate is mixed with 15 per cent. anhydrosulphuric acid (8 parts), the mixture heated on the water-bath for 6—8 hours, and then poured into a large volume of water; the yield of the mixed products is small. On fractionally crystallising the mixture of acids from hot

water, a chloramidobenzenesulphonic acid, identical with the compound just described, is first deposited, and from the mother liquors the isomeride $[\text{Cl} : \text{SO}_3\text{H} : \text{NH}_2 = 1 : 3 : 4]$ is obtained in short, oblong, efflorescent prisms, containing 2 mols. H_2O . F. S. K.

Sulphonation of Metachloronitrobenzene and Metachloraniline. By A. CLAUS and H. BOPP (*Annalen*, 265, 95—107).—The authors can confirm the statement of Post and Meyer (*Ber.*, 14, 1605), that two isomeric sulphonic acids are obtained on heating metachloronitrobenzene with anhydrosulphuric acid at 125° for several hours. Post and Meyer's α -acid, isolated in the manner described by them, has the constitution $[\text{SO}_3\text{H} : \text{NO}_2 : \text{Cl} = 1 : 3 : 5]$, and is formed in larger quantities the more concentrated the anhydro-acid employed. The corresponding *chloride*, $\text{NO}_2 \cdot \text{C}_6\text{H}_3\text{Cl} \cdot \text{SO}_2\text{Cl}$, is an oil; the *amide*, $\text{NO}_2 \cdot \text{C}_6\text{H}_3\text{Cl} \cdot \text{SO}_2 \cdot \text{NH}_2$, crystallises from alcohol and water in small, colourless plates melting at 164 — 165° (uncorr.). The constitution of this acid was proved to be that given above by first reducing it to the corresponding chloramidosulphonic acid (described by Post and Meyer (*loc. cit.*); this compound was then converted into metachlorobenzenesulphamide by first eliminating the amido-group and then treating the product with phosphorus pentachloride and anhydrous ammonia consecutively. Another portion of the chloramidosulphonic acid was treated with sodium amalgam to eliminate the chlorine, and the resulting amidosulphonic acid transformed into the corresponding chlorosulphonic acid by means of the diazo-compound; this substance was finally converted into the sulphamide, which was found to be identical with the metachlorobenzenesulphamide obtained in the first case.

The second acid, obtained by sulphonating metanitrochlorobenzene as described above, has the constitution $[\text{SO}_3\text{H} : \text{NO}_2 : \text{Cl} = 1 : 2 : 6]$; its *chloride*, $\text{NO}_2 \cdot \text{C}_6\text{H}_3\text{Cl} \cdot \text{SO}_2\text{Cl}$, crystallises from ether in yellow prisms, melts at 180° , and is sparingly soluble in chloroform; the corresponding *amide*, $\text{NO}_2 \cdot \text{C}_6\text{H}_3\text{Cl} \cdot \text{SO}_2 \cdot \text{NH}_2$, crystallises from water in long, colourless needles, and decomposes at a high temperature, but without melting. The constitution of this sulphonic acid was determined by the same methods as those employed in the case of the isomeride.

At least two, possibly four, isomeric sulphonic acids are formed when metachloraniline sulphate is heated for 10—12 hours on the water-bath with anhydrosulphuric acid (3—4 parts); on treating the product with water, and precipitating the sulphuric acid with barium hydroxide, there remains in solution a mixture of barium salts which cannot be easily resolved into its constituents, but from which, by fractionally crystallising the free acids from water, pure metachloranilinesulphonic acid $[\text{SO}_3\text{H} : \text{NH}_2 : \text{Cl} = 1 : 2 : 4]$ and an impure isomeride can be obtained. The former has been previously described by Post and Meyer; its constitution was determined by the authors by the same methods as those used in the case of the nitrochlorobenzene-sulphonic acids. The impure isomeride has, most probably, the constitution $[\text{SO}_3\text{H} : \text{Cl} : \text{NH}_2 = 1 : 2 : 4]$. F. S. K.

Sulphonation of Orthotoluidine. By A. CLAUS and F. IMMEL (*Annalen*, 265, 67—87) —Orthotoluidinemetasulphonic acid

is formed in considerable quantity, together with the isomeride $[\text{NH}_2 : \text{Me} : \text{SO}_3\text{H} = 1 : 2 : 4]$, when orthotoluidine sulphate (1 part) is mixed with 50 per cent. anhydrosulphuric acid (2 parts) cooled below 0° , and the mixture kept at this temperature with frequent shaking until it has become a thick, brown mass; the product is then treated with ice-cold water, the cold solution neutralised with barium carbonate, and the barium salts in the filtered solution separated by fractional crystallisation from water. With regard to the 1 : 2 : 4-acid, it may be remarked that the statements of Gerver on this subject are incorrect, but those of Neville and Winther (*Ber.*, 13. 1941) correct; when treated with bromine (1 mol.) in glacial acetic acid solution, it is converted into a crystalline bromo-derivative

the barium salt of which crystallises with 3 mols. H_2O ; when this bromo-acid is treated with bromine (1 mol.) in aqueous solution, it yields dibromotoluidine (m. p. 50°), the platinumchloride of which crystallises with $1\frac{1}{2}$ mols. H_2O . Orthotoluidinemetasulphonic acid, prepared from the barium salt, is very readily soluble in water, from which it crystallises in colourless, transparent needles, containing 1 mol. H_2O ; it is doubtless identical with the acid obtained by the reduction of nitrotoluenesulphonic acid (compare Hayduck, *Annalen*, 172, 204). The *sodium* salt, with $3\text{H}_2\text{O}$, crystallises in needles, and is very readily soluble in water and alcohol. The *barium* salt, with $2\frac{1}{2}\text{H}_2\text{O}$, crystallises in rhombic plates, and is more readily soluble in water than the corresponding salt of the isomeric acid referred to above. The *calcium* salt, with $6\text{H}_2\text{O}$, the *cobalt* salt, and the *nickel* salt are crystalline and readily soluble in water. When the acid is treated with bromine in aqueous solution, it is converted into a dibromo-derivative $[\text{NH}_2 : \text{Me} : \text{Br}_2 : \text{SO}_3\text{H} = 1 : 2 : 4 : 6 : 5]$, which crystallises from boiling water in long, colourless needles, containing 1 mol. H_2O (compare Hayduck, *loc. cit.*); the barium salt of this bromo-acid crystallises from hot water with $8\frac{1}{2}$ mols. H_2O .

Tribromotoluenesulphonic acid $[\text{Br}_3 : \text{Me} : \text{SO}_3\text{H} = 1 : 4 : 6 : 2 : 5]$ can be obtained by decomposing the diazo-derivative of the dibromo-acid just described with cuprous bromide (compare Hayduck, *Annalen*, 174, 354); it crystallises from hot water in small, colourless prisms, and, when treated with highly superheated steam in concentrated sulphuric acid solution, it is readily decomposed into tribromotoluene (m. p. 53°).

Paratoluidinemetasulphonic acid $[\text{NH}_2 : \text{SO}_3\text{H} : \text{Me} = 1 : 3 : 4]$ is formed in large quantities when paratoluidine is sulphonated under the conditions described in the case of the corresponding ortho-compound; the product is washed with cold water to free it from small quantities of the orthosulphonic acid, and then crystallised from hot water, from which it separates in well-defined rhombohedra containing 1 mol. H_2O . It is insoluble in alcohol, reduces am-

moniacal silver nitrate solution, and gives a red coloration on warming with ferric chloride; when boiled with excess of bromine in aqueous solution, it yields a *tribromoparatoluidine*, $[\text{NH}_2 : \text{Br}_2 : \text{Me} = 1 : 2 : 3 : 6 : 4]$, which crystallises in colourless needles melting at 83° (uncorr.).

When aniline sulphate is sulphonated in the cold in the manner described above, the parasulphonic acid alone is obtained; ortho-bromaniline also gives but one sulphonic acid, which is identical with the compound $[\text{NH}_2 : \text{Br} : \text{SO}_3\text{H} = 1 : 2 : 5]$ described by Andrews (*Ber.*, 13, 2126). F. S. K.

Bromisatin-blue. Compounds of Mono- and Di-bromisatin with Piperidine. By C. SCHOTEN (*Ber.*, 24, 2604—2607).—*Dipiperidylbromisatin*, $\text{C}_{18}\text{H}_{24}\text{BrN}_3\text{O}$, is obtained by warming an alcoholic solution of bromisatin with twice the molecular proportion of piperidine. It crystallises in colourless needles, is very sparingly soluble in alcohol, and closely resembles dipiperidylisatin in its behaviour with acids, alkalis, and on warming (compare this vol., p. 928).

Bromisatin-blue is formed when dipiperidylbromisatin is warmed with several times its weight of acetic anhydride, and, on the addition of water to the blue solution is precipitated as a microcrystalline powder. It resembles isatin-blue (*loc. cit.*) in its behaviour with solvents, acids, and alkalis.

Piperidinedibromisatin, $\text{C}_{18}\text{H}_{22}\text{Br}_2\text{N}_2\text{O}_2$, is obtained by adding piperidine to dibromisatin suspended in warm, absolute alcohol. It crystallises in short, pale-yellow prisms, melts at 152° , dissolves sparingly in alcohol, but more easily in ether, and is insoluble in water. It is not affected by boiling with dilute mineral acids or alkalis, or with acetic acid or acetic anhydride, but decomposes with the regeneration of dibromisatin when heated with a mixture of hydrochloric and acetic acids. W. P. W.

Dimethylcarbazole. By E. TAUBER and R. LOWENHERZ (*Ber.*, 24, 2597—2599).—The paper contains a further account of the di-

methylecarbazole  formerly described by the

authors (this vol., p. 834). Dimethylcarbazole can be prepared in two ways, from diamidodimethylcarbazole, and by heating orthodiamidoditoly with a mineral acid above 200° . The first method gives very bad results; the second method is also disadvantageous owing to the difficulty of preparing large quantities of orthodinitroditoly.

Orthodinitroditoly is best obtained as follows:—Well dried meta-dinitrotolidine is made into a paste with a little absolute alcohol and the calculated quantity of 100 per cent. sulphuric acid (for 2 mols.), poured into 15 times as much absolute alcohol, and amyl nitrite (2 mols.) added to the mixture at 10° . The mixture is then heated for some hours to boiling, diluted with water, and the orthodinitroditoly extracted with high boiling petroleum. The nitro-product is

reduced with tin and hydrochloric acid, and the diamido-hydrochloride (m. p. 83°) thus obtained is converted into dimethylcarbazole by heating it with six times the quantity of hydrochloric acid (18 per cent.) in a sealed tube at 230° for 20 hours.

Dimethylcarbazole crystallises from benzene in colourless needles, melts at 219°, is easily soluble in hot benzene, toluene, and alcohol, somewhat easily in ether and carbon bisulphide, and sparingly so in light petroleum, and is very like ordinary carbazole. The *picric acid compound* crystallises in reddish-brown needles, and melts at 192°. The *nitroso-compound* crystallises from alcohol in pure, yellow needles, and melts at 106°. The *acetyl* compound crystallises from alcohol in needles, and melts at 129°. A wood splinter soaked in an alcoholic solution of dimethylcarbazole is coloured red by hydrochloric acid; with isatin, its solution in sulphuric acid gives an indigo-blue. It is distinguished from carbazole by not giving a blue dye on fusion with oxalic acid. When shaken with quinone in acetic acid solution containing a few drops of concentrated sulphuric acid, it gives a deep, indigo-blue solution, and this, on the addition of water, deposits greyish-blue flocks, which dissolve in ether with a bluish-violet colour. Carbazole, under the same treatment, gives a magenta solution, which, on the addition of water, yields reddish-brown flocks, soluble in ether to a red liquid. A table is given of the properties of carbazole and dimethylcarbazole. E. C. R.

Preparation of Hydrobenzoïn and of Deoxybenzoïn. By P. JUILLARD and G. TISSOT (*Chem. Centr.*, 1891, ii, 166; from *Arch. sci. phys. nat. Genève*).—The authors recommend the following method for the preparation of hydrobenzoïn; the product is very pure, but the amount is small: 100 grams of benzaldehyde is reduced with 100 grams of zinc-dust in 500 grams of glacial acetic acid and 10 grams of anhydrous acetic acid. After the zinc-dust has been gradually added, the mixture is heated at 100° for 1½ hours. The resulting liquid is diluted with 4–5 volumes of water and the hydrobenzoïn precipitated with sodium carbonate. It crystallises in beautiful plates, and melts at 134°. The yield is 5–10 per cent. From the oily residue, a few white crystals separated at the end of a few days; the remainder was principally benzyl alcohol and deoxybenzoïn. If dilute acetic acid be employed for the reduction, the product consists chiefly of benzyl alcohol.

Deoxybenzoïn is prepared by the reduction of benzoïn or acetylbenzoïn as follows:—40 grams of benzoïn and 40 grams of zinc are treated with 200 grams of glacial acetic acid, and the reduction is almost perfect. Neither hydrobenzoïn nor acetylhydrobenzoïn is found among the products. Acetylbenzoïn was prepared by heating 2 grams of benzoïn with 10 grams of anhydrous acetic acid for four hours in a tube at 150°, whereby the theoretical quantity was obtained. It crystallises in white needles, and melts at 83°. J. W. L.

Derivatives of Deoxybenzoïn. By J. EPHRAÏM (*Ber.*, 24, 2820–2827).—*Deoxybenzoïnorthodicarboxylic acid*,

is obtained by heating 1:2-carboxyphenylacetic acid (10 parts) with an equal weight of phthalic anhydride, and sodium acetate (1 part) in an oil-bath at 180—190°, the reagents being anhydrous, treating the dark-coloured melt with hot water, dissolving in cold sodium hydroxide solution, precipitating the filtrate with hydrochloric acid, treating the precipitate with cold alcohol, and crystallising from glacial acetic acid; it forms white needles and melts at 238—239°; the *silver salt* separates in white, feathery needles on adding silver nitrate to a solution of the ammonium salt. When the acid (2 grams) is heated with fuming hydriodic acid (5 c.c.) and amorphous phosphorus (1 gram) in a sealed tube at 160° for 2—3 hours, and the melt extracted with sodium carbonate solution, dibenzylorthodicarboxylic acid, $C_6H_4(C_6H_4\cdot COOH)_2$, melting at 225°, separates on the addition of hydrochloric acid. The acid, $C_{16}H_{11}O_5N$, is formed when deoxybenzoïnorthodicarboxylic acid (1 gram) is heated with concentrated alcoholic ammonia in a sealed tube for 12 hours; it crystallises from alcohol in white rhombohedra, and its constitution is represented either by $COOH\cdot C_6H_4\cdot CH:C<\overset{NH}{\underset{C_6H_4}{\curvearrowright}}CO$ or by $COOH\cdot C_6H_4\cdot C<\overset{CH}{\underset{NH\cdot CO}{\curvearrowright}}C_6H_4$. This, when heated on the water-bath with twice its weight of phosphorus oxychloride, yields the compound, $C_6H_4<\overset{CO\cdot N\cdot CO}{\underset{O\cdot CH}{\curvearrowright}}C_6H_4$.

When deoxybenzoïnorthodicarboxylic acid is dissolved in absolute alcohol, the cooled solution saturated with hydrogen chloride, and water added, the *anhydride*, $O<\overset{CO\cdot C_6H_4\cdot CH_2}{\underset{CO\cdot C_6H_4\cdot CO}{\curvearrowright}}$, is precipitated; it crystallises from alcohol in white needles, melts at 260°, and is insoluble in cold alkalis. The *oximidolactone*, $C_6H_4<\overset{CH_2}{\underset{COO\cdot N}{\curvearrowright}}C\cdot C_6H_4\cdot COOH$ or

$CO<\overset{C_6H_4}{\underset{O\cdot N}{\curvearrowright}}C\cdot CH_2\cdot C_6H_4\cdot COOH$, is produced when the acid is dissolved in alkali and treated with hydroxylamine; it crystallises from alcohol in delicate, rose-coloured needles, and melts at 229—230°; the *lactone*, $COOH\cdot C_6H_4\cdot CH_2\cdot CH<\overset{C_6H_4}{\underset{O}{\curvearrowright}}CO$ or $COOH\cdot C_6H_4\cdot CH<\overset{CH_2}{\underset{O\cdot CO}{\curvearrowright}}C_6H_4$,

is obtained when the acid is treated with five times the calculated quantity of sodium amalgam in alkaline solution; it separates from alcohol in monosymmetric crystals, $a : b : c = 0.8962 : 1 : 0.7478$; $\beta = 61^\circ 43'$, and melts at 201°. The *barium salt* of the bibasic acid, $COOH\cdot C_6H_4\cdot CH_2\cdot CH(OH)\cdot C_6H_4\cdot COOH$, is formed when the lactone is boiled with barium hydroxide, and, on adding the silver nitrate to the resulting solution, the *silver salt* is precipitated.

The author has separated a small quantity of a bye-product, $C_{16}H_{10}O_4$, in the preparation of deoxybenzoïnorthodicarboxylic acid by the above-described method; it crystallises from glacial acetic acid in white needles, melts at 250°, and is not identical with deoxybenzoïnorthodicarboxylic anhydride. It yields an acid, $C_{16}H_{10}O_5$, melting at 196°, which thus appears to be isomeric with deoxybenzoïnorthodicarboxylic acid.

Synthesis of Hydroxyxanthenes. By B. NESSLER (*Chem. Centr.*, 1891, ii, 61; from *Schweiz. Wochenschr. Pharm.*, 29, 186).—Similarly to the formation of xanthone from orthohydroxybenzoic acid, hydroxyxanthenes may be prepared from dihydroxy-acids. From dihydroxybenzoic acid, dihydroxyxanthone is formed; from a mixture of salicylic and dihydroxybenzoic acids, a monohydroxyxanthone is obtained; and the phenols, resorcinol, orcinol, quinol, and phoroglucinol unite with hydroxy-acids with formation of corresponding hydroxyxanthenes.

J. W. L.

Derivatives of Lapachic Acid. By E. PATERNÒ and L. CABERTI (*Gazzetta*, 21, 374—381).—Monobromolapachic acid may be reduced by suspending it in very dilute caustic potash and treating with zinc dust; after half an hour, the solution is filtered, saturated with carbonic anhydride, and, as soon as the resin is deposited, the liquid is filtered and acidified with hydrochloric acid, when a flocculent precipitate of lapachic acid falls. This shows Hooker and Green's opinion, that monobromolapachic acid is a derivative of lapachone (Abstr., 1889, 999), is incorrect.

Paternò and Minunni (Abstr., 1890, 1310) showed that lapachic acid, when treated with thiophen and sulphuric acid, yields a condensation product; the authors find that the reaction occurs between the thiophen and lapachone formed by the action of sulphuric acid on the lapachic acid. Lapachone (1 part) and thiophen (1 part) are dissolved in glacial acetic acid (1 vol.) and concentrated sulphuric acid (1 vol.) added; after five hours, the emerald-green solution is poured into much water, the bulky, blue precipitate collected and washed, first with water, then with a mixture (equal parts) of alcohol and water, and finally dried. The substance is now of an intense, sky-blue colour, and is soluble in strong alcohol, ether, chloroform, and light petroleum, yielding a blue solution; it dissolves in acetic acid and in sulphuric acid, from which it is precipitated by water, a part being resinified. In solution this substance seems to be unaltered by hydrochloric acid or sodium amalgam, but is slowly oxidised by nitric acid and at once decolorised by chlorine-water. It contains sulphur, but could not be obtained sufficiently pure for quantitative analysis.

On passing dry hydrogen chloride through a solution of lapachic acid in glacial acetic acid, the solution becomes brownish-red, and, on pouring it into water, yields lapachone and a trace of another substance, probably the compound obtained when lapachic acid is treated with nitric acid. If a solution of lapachone and thiophen in glacial acetic acid is saturated with dry hydrogen chloride and allowed to remain for some days, the blue compound described above is obtained. A solution of lapachic acid (1 part) in glacial acetic acid, on treatment with fused zinc chloride (10 parts), yields nothing but pure lapachone after remaining for 18 hours. Zinc chloride also effects the condensation of lapachone with thiophen, but much resinous matter is produced at the same time. Lapachic acid is partially converted into lapachone by calcium chloride, but is seemingly unaltered by stannous chloride in alcoholic solution.

An improved process for the preparation of lapachic acid is the fol-

lowing:—The crude product (100 grams), obtained by boiling the shavings or sawdust of lapacho wood with sodium carbonate, and decomposing the solution with hydrochloric acid, is boiled with baryta-water (30–35 grams barium hydrate in 15 litres of water). On filtration and precipitation with hydrochloric acid, the lapachic acid is generally pure enough to be at once recrystallised from alcohol.

W. J. P.

Melting Points of Binary Systems of Hydrocarbons. By L. VIGNON (*Compt. rend.*, 113, 133–136).—The hydrocarbons employed were naphthalene, diphenyl, phenanthrene, triphenylmethane, and anthracene, which were mixed in pairs in various proportions.

The mixtures may be divided into two groups, namely, (a) those that contain anthracene and have a melting point which rises as the proportion of anthracene increases, but is always higher than the mean calculated melting point; and (b) those that contain no anthracene. In the latter group, the melting point is always lower than the mean calculated melting point, and the curves have a characteristic form, showing a point of reversal which corresponds in the various cases to the following mixtures: naphthalene, 2 mols., and diphenyl, 1 mol.; naphthalene, 2 mols., and phenanthrene, 1 mol.; naphthalene, 1 mol., and triphenylmethane, 1 mol.; diphenyl, 2 mols., and phenanthrene, 1 mol.; diphenyl, 2 mols., and triphenylmethane, 1 mol.

C. H. B.

Truxillic Acids. By J. HOMANS, R. STELTZNER, and A. SUKOW (*Ber.*, 24, 2589–2592).—When α -truxillic acid is treated with a small quantity of fuming nitric acid (1.52), it dissolves, and two isomeric mononitro-acids are formed. The one acid (b) crystallises from the solution on cooling, the other (a) is obtained by diluting with water and is purified by crystallisation from alcohol.

a-Nitro- α -truxillic acid, $[\text{C}_6\text{H}_7(\text{NO}_2)\text{O}_2]_2$, forms small prisms, melts at 228–229°, and is easily soluble in alcohol, ether, and acetic acid, sparingly in benzene. It is not attacked by potassium permanganate in alkaline solution, and is thus distinguished from nitrocinnamic acid. The salts do not crystallise. *Ethyl a*-nitro- α -truxillate crystallises from alcohol in yellow needles and melts at 138°.

b-Nitro- α -truxillic acid is insoluble, or only sparingly soluble, in all solvents, melts at 290° with decomposition, and does not reduce permanganate. The *silver* salt forms a white, granular precipitate. The *barium* salt is easily soluble in water and crystallises in bright-yellow needles.

β - and γ -truxillic acids each yield only one mononitro-acid.

Nitro- β -truxillic acid is, when first obtained, an oil which is purified with difficulty by recrystallisation from alcohol. It melts at 216°, is easily soluble in ether, acetic acid, and chloroform, sparingly in benzene, and does not reduce potassium permanganate.

Nitro- γ -truxillic acid forms small prisms, melts at 293°, is easily soluble in alcohol and acetic acid, insoluble in benzene, and slowly reduces potassium permanganate.

The amido-derivatives of α -truxillic acid are obtained by reducing the nitro-derivatives with tin and hydrochloric acid, precipitating the

tin with sulphuretted hydrogen, and concentrating the filtrate in a vacuum on the water-bath.

a-Amido-a-truxillic acid is obtained, in scales of silvery lustre, by precipitating a solution of the hydrochloride with sodium acetate, and is purified by precipitation from acetone by petroleum. The *hydrochloride* forms very soluble needles.

b-Amido-a-truxillic acid crystallises from water in needles. The *hydrochloride* forms needles, and is less soluble than the *a-amido-acid*. The *sulphate* is obtained in beautiful, sparingly soluble needles on adding the theoretical quantity of sulphuric acid to a solution of the hydrochloride.

b-Diazo-a-truxillic acid nitrate, $[C_9H_7(N_2NO_3)O_2]_2$, is obtained in pale-yellow needles by adding sodium nitrite (1.84 grams) to an ice-cold solution of the hydrochloride of the amido-acid (5 grams) in a small quantity of water and nitric acid (5 cc.). It is easily soluble in water, and yields a ponceau-red dye with sodium β -naphtholdisulphonate, which does not, however, dye cotton directly.

b-Hydroxy-a-truxillic acid is obtained by adding the calculated quantity of sodium nitrite to a solution of the amido-hydrochloride in concentrated sulphuric acid. The mixture is diluted with water and heated to boiling, when the hydroxy-acid is obtained as a yellow precipitate. It crystallises from alcohol in colourless flocks, is sparingly soluble in most solvents, does not melt at 360° , dissolves in cold soda, and is precipitated by acids. The *calcium* salt is obtained by boiling the acid with calcium carbonate, is easily soluble in water, and is precipitated on the addition of alcohol.

b-Acetylhydroxy-a-truxillic acid is obtained by the action of acetic anhydride and sodium acetate on the hydroxy-acid; it crystallises from acetic acid in tufts of needles, and melts at 244° . E. C. R.

Essence of Lemons. By V. OLIVERI (*Gazzetta*, 21, 318—330).—Recently prepared essence of lemons is a canary-yellow, oily liquid, of a pungent acid taste. Its sp. gr. is 0.860 at 16° , and its specific rotatory power $[\alpha]_D$ at 16° varies from $+69.75^\circ$ to $+75.10^\circ$.

On distilling essence of lemons which has been steam-distilled and dried over fused potassium carbonate, three principal fractions are obtained. The first portion, boiling at 170 — 170.5° , constitutes about one-fifteenth part of the whole, and has a sp. gr. of 0.8867 at 0° and a specific rotatory power $[\alpha]_D = +64.82^\circ$ at 16° . It is a colourless, mobile liquid, having the characteristic odour of the essence, and has the composition of a terpene, $C_{10}H_{18}$.

Limonene Tetrabromide, $C_{10}H_{16}Br_4$.—This is obtained when the limonene (1 vol.) is dissolved in a mixture of alcohol (4 vols.) and ether (4 vols.), and bromine (0.7 vol.) dropped into the solution cooled to 0° . The product, after washing with cold alcohol and dissolving in boiling ethyl acetate, is obtained as an oil which, after a time, solidifies to a crystalline mass melting at 31° . The *dihydrochloride*, $C_{10}H_{18}Cl_2$, is prepared by passing excess of hydrogen chloride through a mixture of equal weights of ether and the limonene; the ether is evaporated, and the product dried on a porous plate and recrystallised from alcohol. It forms small, colourless, six-sided tables melting at

50°; it agrees in properties with the dihydrochloride prepared by Wallach.

The second fraction from lemon oil boils between 176° and 178° and includes about nine-tenths of the whole; it is a mobile, colourless liquid having a sp. gr. of 0.8990 at 0° and a specific rotatory power $[\alpha]_D = +76.75^\circ$. Vapour density determinations and analyses show it to have the composition $C_{10}H_{16}$. The *tetrabromide*, $C_{10}H_{16}Br_4$, prepared as above, melts at 102–103°; the *dihydrochloride*, $C_{10}H_{18}Cl_2$, crystallises in scales soluble in alcohol, and melts at 50°.

The third fraction boils at 240–242°; in fresh lemon oil, the proportion is very small, but much larger quantities are obtained from old oil, along with polyterpenes boiling at 250–340°. The portion boiling at 240–242° consists of a sesquiterpene, $C_{15}H_{24}$; it is a viscous, yellowish liquid, of sp. gr. = 0.9847 at 0°, very slowly volatile with steam, and optically inactive. It is soluble in ether, and sparingly soluble in alcohol. The *tetrabromide*, $C_{15}H_{24}Br_4$, is a heavy, colourless oil, which does not solidify at –20°. The *dihydrochloride*, $C_{15}H_{26}Cl_2$, separates from its cooled alcoholic solution as an oil.

Detection of Oil of Turpentine as an Adulterant in Essence of Lemons.—The sophistication of essence of lemons by turpentine oil is difficult to detect, owing to the percentage composition of the two oils being identical and their boiling points and densities being almost the same.

The author finds that the readiest method of detecting the fraud is to observe the specific rotatory power. As the adulterant most frequently employed is French turpentine oil, having a specific rotatory power of $[\alpha]_D = -27.0^\circ$ about, its presence in lemon oil, having a specific rotation $[\alpha]_D = +60.0^\circ$, is at once betrayed; the amount of the adulterant may be easily calculated, as the rotatory power of the mixture is the algebraic sum of the rotatory powers of its constituents taken in the proportions in which they are present. Even when the adulterant is a dextrorotatory oil, such as Russian or English turpentine, the change in the rotatory power is so great as to at once betray its presence.

The author gives tables for calculating the percentage of the adulterant present from its rotatory power. W. J. P.

Hygroscopic Behaviour of Camphor and Thymol. By G. CLAUTRIAU (*Lic.*, 24, 2612–2614).—In the course of the physiological investigation of the irritability of a fungus, Errera arrived at the conclusion that camphor has a considerable hygroscopic capacity which is not shared by thymol. This view is confirmed by the author's experiments. A small, tared vessel containing camphor was supported in the middle of a glass receiver of 3 litres capacity, which was closed by a cover smeared with camphorated lard. To avoid loss of camphor by evaporation, the walls of the receiver were completely covered with a layer of camphor, and the water employed to keep the air moist was also saturated with camphor. Similar precautions were adopted in the case of thymol. After deducting the weight of water found to condense on the tared vessel in a blank experiment, numbers were obtained indicating that 10 grams of camphor absorbed 0.022

and 0.032 gram of water in two experiments, whilst thymol showed no appreciable increase in weight. Dry camphor, although it attracts a comparatively small amount of water, does so with such energy that its weight increases even in air containing but little moisture. On the other hand, the condensed water is readily removed, even under the influence of less moist camphor. W. P. W.

Compounds of Camphors with Aldehydes. By A. HALLER (*Compt. rend.*, 113, 22—26).—If the constitution of camphor is correctly represented by the formula $C_8H_{14} \begin{smallmatrix} CH_2 \\ | \\ CO \end{smallmatrix}$, it may be expected to form, with aldehydes, condensation products having the general formula $C_8H_{14} \begin{smallmatrix} C:CH \cdot R \\ | \\ CO \end{smallmatrix}$.

After various unsuccessful or only partially successful attempts to verify this idea, it was found that many aldehydes react with sodium-camphor according to the general equation $C_8H_{14} \begin{smallmatrix} CHNa \\ | \\ CO \end{smallmatrix} + R \cdot CHO = C_8H_{14} \begin{smallmatrix} C:CH \cdot R \\ | \\ CO \end{smallmatrix} + NaOH$, and that the substances thus obtained furnish reduction products having the general formula

Benzalcamphor, $C_{10}H_{14}O \cdot CHPh$, is obtained by treating sodium-camphor with benzaldehyde. Camphor (150 grams) dissolved in toluene (400 grams) is heated with sodium (15 grams) in a reflux apparatus until the metal is dissolved, and the benzaldehyde (105 grams) is added to the cooled and washed product. The resulting liquid is washed with water and dried, the toluene is distilled off, and the residue is heated as long as camphor volatilises. The benzalcamphor separates from the alcoholic extract in brilliant prisms. It melts at 95—96°, and is soluble also in ether, benzene, and toluene. It exists in three physically isomeric modifications, dextro-rotatory and lævorotatory, prepared respectively from dextro-rotatory and lævorotatory camphor, and racemic, prepared by mixing equal proportions of the active varieties. The racemic modification melts at 78°. Benzalcamphor, when reduced with sodium amalgam, yields **benzylcamphor**, $C_{10}H_{15}O \cdot CH_2Ph$, which resembles, optically, the modification from which it is prepared.

Cuminalcamphor, $C_{10}H_{14}O \cdot CH \cdot C_6H_4Pr$, prepared in a similar way from cumaldehyde, forms long, brittle prisms, soluble in the same menstrua as benzalcamphor. It melts at 62°, and is dextro-rotatory. On reduction, it yields **cuminylicamphor**, $C_{10}H_{15}O \cdot CH_2 \cdot C_6H_4Pr$, a yellow, oily liquid which boils between 280° and 290° under a pressure of 50 mm.

Cinnamalcamphor, $C_{10}H_{14}O \cdot CH \cdot CH \cdot CHPh$, was obtained as a yellowish, viscous, uncrystallisable liquid, boiling at 280° under a pressure of 50 mm.

Methylsulcinylicamphor, $C_{10}H_{14}O \cdot CH \cdot C_6H_4 \cdot OMe$, separates from alcohol in beautiful crystals melting at 92—94°. On reduction, it

yields *methylsaligenylcamphor*, $C_{10}H_{18}O \cdot CH_2 \cdot C_6H_4 \cdot OMe$, which crystallises from alcohol in white, rhomboidal plates, and melts at 49° . The corresponding ethyl compounds were also prepared. JN. W.

Derivatives of Cyanocamphor. By A. HALLER (*Compt. rend.*, 113, 55—59).—Sodiumcyanocamphor, $C_8H_{14} \begin{smallmatrix} \text{CNa} \cdot \text{CN} \\ \text{CO} \end{smallmatrix}$ (*Compt. rend.*, 112, 1477), reacts with alkyl iodides and acid chlorides to form derivatives having the general formula $C_8H_{14} \begin{smallmatrix} \text{CR} \cdot \text{CN} \\ \text{CO} \end{smallmatrix}$.

To prepare the alkyl derivatives, cyanocamphor (1 mol.) is mixed in a reflux apparatus with the alkyl iodide (rather more than 1 mol.); potash (1 mol.), dissolved in its own weight of water, is then gradually added from a tap funnel, and the whole is heated for an hour. The excess of the iodide having been distilled off, the upper oily layer of the residual liquid is treated with aqueous potash to dissolve any undecomposed cyanocamphor, and is then extracted with ether. The dry ethereal solution is evaporated, and the residual, oily product is rectified in a vacuum.

To prepare the acid derivatives, an alcoholic solution of sodium cyanocamphor is treated in the cold with the theoretical amount of an ethereal solution of the acid chloride, and the reaction is completed with the aid of heat. The product is then taken up with water and extracted with ether, and the ethereal solution is washed with aqueous potash, dried, and allowed to evaporate. The residue consists of a solution of the acid derivative in the ethyl salt of the acid, from which crystals of the former separate after a time.

The alkyl and acid derivatives of cyanocamphor thus obtained are colourless, oily liquids, or crystalline solids, soluble in alcohol, ether, and hydrocarbons, but insoluble in water and alkalis.

Methylcyanocamphor is a liquid, which smells of grass, and boils at 170 — 180° under a pressure of 36 mm. Its molecular rotatory power is $[\alpha]_D = +107.69^\circ$. (The determinations of the rotatory power of the various derivatives were made on toluene solutions containing $\frac{1}{2}$ gram-mol. per litre.)

Ethylcyanocamphor is a liquid, which smells of grass and hydrocyanic acid, and boils at 163 — 165° under a pressure of 21 mm. Its molecular rotatory power is $[\alpha]_D = +120.71^\circ$.

Normal propylcyanocamphor crystallises in needles and has an aromatic smell and fresh taste. It melts at 46° , and boils at 150° under a pressure of 20 mm. Its molecular rotatory power is $[\alpha]_D = +126.16^\circ$.

Benzylcyanocamphor melts at 58 — 59° . Its molecular rotatory power is $[\alpha]_D = +93.62^\circ$.

Orthonitrobenzylcyanocamphor melts at 104 — 105° . Its molecular rotatory power is $[\alpha]_D = +68.37^\circ$.

Benzoylcyanocamphor crystallises in thin, rectangular plates, and melts at 105° . It is decomposed by strong aqueous potash into potassium-cyanocamphor and potassium benzoate.

Orthitoluylcyanocamphor forms hard crystals, which are larger than those of its homologue. JN. W.

Methyl and Ethyl Methylcamphocarboxylates. Preparation of Methylcamphor. By J. MINQUIN (*Compt. rend.*, 112, 1369—1372).—The methyl camphocarboxylate used was a colourless oil boiling at 155—160° under a pressure of 15 mm. Its rotatory power in alcohol $[\alpha]_D = +61.90^\circ$.

Methyl Methylcamphocarboxylate.—Methyl camphocarboxylate (30 grams) and methyl iodide (25 grams) are boiled together for about two hours in a reflux apparatus with the addition of five or six portions of 20—30 c.c. of methyl alcohol in which 3.2 grams of sodium has been dissolved. Water is added and the precipitate taken up with ether. The ethereal solution, on evaporation, yields colourless crystals, soluble in alcohol, but more so in ether. The yield is about 15 grams of the pure product. There remains an oily liquid distilling at the same temperature as the camphocarboxylate and still containing, after distillation, a certain quantity of this solid. Methyl methylcamphocarboxylate melts at 85°; its rotatory power in alcohol ($\frac{1}{2}$ mol. per litre) is $[\alpha]_D = +17.25^\circ$.

Ethyl methylcamphocarboxylate is similarly prepared. It is a crystalline substance melting at 60—61°, soluble in alcohol and ether, and has a rotatory power $[\alpha]_D = +13.8^\circ$.

Methylcamphor, $C_8H_{14} \begin{smallmatrix} \text{CHMe} \\ | \\ \text{CO} \end{smallmatrix}$.—The methylcamphocarboxylates described above are not hydrolysed by treatment during four days with alcoholic potash in a reflux apparatus, but the change is readily brought about by heating in sealed tubes at 130—140°. Water is added to the contents of the tubes and the precipitate taken up with ether. The wash water contains potassium carbonate; the ethereal solution washed, dried, and evaporated, gives a crystalline substance having the odour of camphor and melting at 37—38°. Its rotatory power (1 mol. in 1 litre of alcohol) is $[\alpha]_D = 270.65$.

The oily residue is hydrolysed in a reflux apparatus, when the camphocarboxylic ether is readily converted into camphor and a further quantity of the substituted ethers is obtained. W. T.

Reduction of Apione. By G. CIAMICIAN and P. SILBER (*Ber.*, 24, 2608—2612).—Dibromapione (Abstr., 1888, 1100) is best prepared by rapidly adding the calculated quantity of bromine to a warm solution of apiolic acid in acetic acid, and immediately pouring the product into water. After addition of some sulphurous acid, the dibromapione is filtered, and purified by crystallisation from alcohol. The yield amounts to 20 grams from 13 grams of apiolic acid.

Apione (Abstr., 1886, 848) can be prepared with advantage by reduction of dibromapione, and as a small proportion of the phenol obtained by reducing apione is also formed in the reaction, the two reductions can be carried on in the same operation. Dibromapione is dissolved in 20 parts of alcohol and the boiling solution gradually saturated with sodium. The product is then diluted with twice its volume of water, distilled on a water-bath to remove alcohol, and the recovered apione again treated with sodium and boiling alcohol, the process being repeated several times until all is reduced. The alkaline

liquors from each reaction are shaken out with ether to remove any dissolved apione, then acidified, and the reduction product extracted with ether, which is subsequently removed by distillation. The reduction product of apione, a dimethoxyhydroxybenzene, $C_6H_3(OMe)_2OH$, is a thick oil, which slowly solidifies in a freezing mixture, melts at 24° , boils at $251-252^\circ$, and has a pronounced phenolic odour. With concentrated soda and potash solutions, it forms salts which crystallise in needles and dissolve easily in water. The acetyl derivative, $C_6H_3(OMe)_2OAc$, crystallises from alcohol in large, colourless forms, and melts at 68° . When heated with hydrochloric acid at 100° , charring occurs, and methyl chloride is obtained, together with a crystalline compound which forms an acetyl derivative melting at about 166° . On methylation in the usual way, the reduction product is converted into a trimethoxybenzene, $C_6H_3(OMe)_3$, boiling for the most part at 248° ; this, although it solidifies but slowly in a freezing mixture, melts at 14° , and, moreover, does not seem to yield a nitro-derivative, is regarded by the author as possibly identical with Will's 1 : 2 : 4-trimethoxybenzene (Abstr., 1888, 457). Further experiments to decide this question are promised. W. P. W.

Adonin, a Glucoside from Adonis amurensis. By Y. TAHARA (*Ber.* 24, 2579—2582).—The author has prepared the glucoside from *Adonis amurensis* in order to compare it with adonidin, the glucoside from *Adonis vernalis*. The following method of extraction was used. The air-dried root (1.7 kilograms) was cut fine and extracted five times with 90 per cent. alcohol. On distilling off the alcohol, a brown mass was obtained which dissolved in water. The concentrated aqueous solution was made strongly alkaline and extracted with chloroform, the chloroform distilled off, and the residue dissolved in alcohol and fractionally precipitated with ether. In this way a yellowish, gummy mass was obtained which yields a white powder. The yield amounts to 1.94 per cent. on the material extracted. This glucoside the author calls adonin. On analysis, it gave numbers corresponding with the formula $C_{24}H_{40}O_9$.

Adonin is easily soluble in water, alcohol, chloroform, and acetic acid, insoluble in ether. The aqueous solution has a very bitter taste. It dissolves in concentrated nitric acid with an indigo blue colour; the same coloration is obtained on adding nitric acid to the acetic acid solution; with concentrated sulphuric acid it gives a deep red, with hydrochloric acid a rose-red. In aqueous solution, it is easily decomposed by mineral acids, and a few drops of hydrochloric acid in the cold convert it into a sugar and a resinous substance easily soluble in ether. Acetic acid and alkalis do not, however, decompose it. The aqueous solution is precipitated by gallic acid, picric acid, Meyer's reagent, gold chloride, &c. On shaking with benzoic chloride and potassium hydroxide, it gives a benzoyl derivative. Its toxic action is similar to that of adonidin, but is weaker. E. C. R.

Action of Methyl Alcohol on Pyrroline. By M. DENNSTEDT (*Ber.*, 24, 2559—2563).—The author has examined the products obtained when a mixture of methyl alcohol and pyrroline is passed over

heated zinc dust. The product consists of an oil together with a small quantity of a compound which crystallises in the cooler parts of the tube, and is probably a tripyrrolylmethane derivative; the latter dissolves in alcohol and acetic acid to a dark-red solution, and dyes wool and silk brown. The oil was fractionally distilled, the different fractions heated in sealed tubes with acetic anhydride and sodium acetate at 180—190°, and the products examined. The fraction boiling below 135° contained unaltered pyrroline, aldehydic and ketonic condensation products of methyl alcohol, and a very small quantity of 1-methylpyrroline. The fractions 137—140° and 142—143° gave a mixture of acetylmethylpyrrolines which distils at 230—240° and is partially solid. The solid compound which is the main product melts at 86°, and on condensation with benzaldehyde gives 2-methylpyrrolyl cinnamyl ketone melting at 193—194°. The oily product yields 3-methylpyrrolyl cinnamyl ketone melting at 148—149°. The greater part of the product is contained in the fraction boiling at 147—149°, and consists of 2-methylpyrroline, which yields the acetyl compound melting at 86°. From the last fractions, a compound was obtained which the author believes to be 2:3-dimethylpyrroline, together with a trimethylpyrroline.

Ethyl alcohol and pyrroline yield as chief product the ethylpyrroline boiling at 163—165°.

The author has also prepared the dimethylindole from the methylpyrroline boiling at 147—148°, and finds that it readily yields an acetyl compound when heated with acetic anhydride and sodium acetate at 190°. This *acetyldimethylindole* crystallises from dilute alcohol, melts at 215—217°, and is not altered by boiling with dilute alkali. The author thinks that the formation of this acetyldimethylindole is evidence that the methylpyrrol boiling at 147—148° is 3-methylpyrroline.

E. C. R.

Action of Hydroxylamine on the Pyrrolines. By G. CIAMICIAN and C. U. ZANETTI (*Gazzetta*, 21, 231—247).—*Succinazone* (*succinodiphenyldihydrazone*), $C_{20}H_{14}(OH.N_2.HPh)_2$, prepared by treating a boiling aqueous solution of the oxime with an acetic acid solution of phenylhydrazine, crystallises from boiling alcohol in yellow scales, and melts at 124—125°.

Diphenyldipyrroline, $C_{20}H_{14}N_4$, is prepared by treating the previous compound (6 grams) in the cold with concentrated hydrochloric acid (100 c.c.) and precipitating the solution with water. It crystallises from ethyl acetate in tufts of white or yellowish needles, and melts at 184—185° with decomposition. It dissolves readily in benzene and boiling ethyl acetate, sparingly in ethyl alcohol, and is almost insoluble in light petroleum. It is a feeble base and dissolves in concentrated acids without decomposition, but is reprecipitated from its solutions by water. On treating its sulphuric acid solution with a crystal of potassium dichromate, an intense blue coloration is obtained. It probably has a constitution analogous to that of Ach's dimethyldiphenyldipyrroline (*Annalen*, 253, 44). On treating an alcoholic solution of 1-ethylpyrroline with hydroxylamine hydrochloride and sodium carbonate, succinaldoxime and ethylamine are

formed. From this, the authors conclude that the action of hydroxylamine on pyrroline may be rigorously represented by the equation

α-Methyllevulindioxime, $\begin{array}{c} \text{CHMe}\cdot\text{CH}\cdot\text{NOH} \\ | \\ \text{CH}_2\cdot\text{CMe}\cdot\text{NOH} \end{array}$, prepared by boiling an alcoholic solution of 2:4'-dimethylpyrroline with hydroxylamine hydrochloride and sodium carbonate, crystallises when pure from ether in pale-yellowish needles or prisms, melts at 87–90°, dissolves in water and alcohol, and sparingly in ether, and has the general properties of an oxime. It readily reduces an alkaline copper solution and ammoniacal silver nitrate. The sodium derivative, $\text{C}_6\text{H}_{10}\text{N}_2\text{Na}_2\text{O}_2$, is a whitish powder which deliquesces in the air.

αβ'-Dimethyltetramethylenediamine,

is obtained by reducing a solution of *α*-methyllevulindioxime in absolute alcohol with metallic sodium. It is a colourless, fuming liquid with a penetrating disagreeable odour, and boils at 175°. The *oxalate*, $\text{C}_4\text{H}_8\text{Me}_2(\text{NH}_2)_2\cdot\text{H}_2\text{C}_2\text{O}_4$, crystallises in slender needles melting at 244°, with decomposition. It is hygroscopic and very soluble in water. The *platinochloride*, $(\text{C}_6\text{H}_{16}\text{N}_2)_2\cdot\text{H}_2\text{PtCl}_6$, forms small, orange-coloured crystals very soluble in boiling water. The *aurochloride* crystallises in tufts of yellow needles.

Acetophenoneacetonedioxime, $\text{CPh}(\text{NOH})\cdot[\text{CH}_2]_2\cdot\text{CMe}\cdot\text{NOH}$, prepared by the action of hydroxylamine on 2:5'-methylphenylpyrroline, crystallises when pure in small, white needles, melts at 108°, and dissolves in alcohol, acetic acid, and ethyl acetate, but is almost insoluble in water and light petroleum. It is readily soluble in solutions of the alkalis, but is reprecipitated by dilute acids.

S. B. A. A.

Pyridyl Ketones. By C. ENGLER (*Ber.*, 24, 2525–2527).—The ketone derivatives of pyridine have been little studied hitherto, on account of the difficulty experienced in obtaining them in quantity; in view, however, of the close relations existing between these compounds and the alkaloids, the author has subjected them to further investigation. The results obtained up to the present are given in the following abstracts.

H. G. C.

Methyl *α*-Pyridyl Ketone. By C. ENGLER and P. ROSUMOFF (*Ber.*, 24, 2527–2529).—All attempts to obtain this ketone by the action of acetic chloride on pyridine in presence of aluminium chloride were without success. It was therefore prepared by distilling calcium picolinate with a slight excess of calcium acetate; a portion of the crude distillate was treated with phenylhydrazine or its sulphonic acid, the condensation product reconverted into the ketone, and the boiling point of the latter determined. The remainder of the crude product was then purified by fractional distillation.

Methyl α -pyridyl ketone, $C_5NH_4 \cdot COMe$, is a colourless liquid, which boils at 192° (uncorr.), has a very characteristic odour, and becomes yellow in the air. The *hydrochloride* and *sulphate* form deliquescent masses, the *platinochloride* is a sparingly soluble crystalline powder, and the *dichromate* forms orange-yellow crystals. The *picrate* crystallises from alcohol in yellow needles melting at 131° , the *mercurochloride* melts at 150° , the *methiodide* at 161° , the *ethiodide* at 205° , and the *chlorido-additive product* at 116° .

The *oxime*, $C_5NH_4 \cdot CMe \cdot NOH$, is obtained by mixing the ketone with fused hydroxylamine hydrochloride, adding aqueous soda, and gently warming. It crystallises from a mixture of ether and light petroleum in white needles, and melts at 120° . The *phenylhydrazone*, $C_5NH_4 \cdot CMe \cdot N_2HPh$, forms beautiful, yellow crystals, and melts at 155° ; the *phenylhydrazonesulphonic acid* is obtained as a yellow precipitate by boiling the ketone with an aqueous solution of phenylhydrazinesulphonic acid, and is purified by repeated solution in ammonia and reprecipitation by acids; it does not melt at 300° and is insoluble in neutral solvents. To reconvert it into the ketone, it must be boiled with hydrochloric acid, mixed with ferric chloride to oxidise the hydrazine, and saturated with caustic soda, the solution being then extracted with ether.

On reduction with sodium amalgam, the ketone yields a solid pinacone, and a liquid pyridinalkine. The products of the action of sodium have not been isolated.

H. G. C.

Ethyl α -Pyridyl Ketone and its Conversion into Pseudoconhydrine. By C. ENGLER and F. W. BAUER (*Ber.*, 24, 2530—2536).

—*Ethyl α -pyridyl ketone* is obtained in a manner similar to the methyl base by distilling a mixture of calcium picolinate and propionate, and is a characteristic smelling liquid, which boils at 205° (uncorr.) and quickly becomes brown in the air; it is soluble in alcohol, ether, and acids, but almost insoluble in water. It yields a deliquescent *hydrochloride*, a crystalline *platinochloride*, and also an *aurochloride*, a *chromate*, and a *picrate*. The *mercurochloride*, $C_5H_4NO \cdot HgCl_2$, may be crystallised from mercuric chloride solution; the *methiodide* and *ethiodide* are obtained by heating the base with the alkyl iodide and alcohol in a sealed tube, the latter compound melting at 160° ; the *chlorido-additive product* melts at 124° . The *oxime*, $C_5NH_4 \cdot CEt \cdot NOH$, forms needles melting at 106° , and yields an *acetyl* and a *benzoyl* derivative melting at 46° and 69° respectively. The *phenylhydrazone*, $C_5NH_4 \cdot CEt \cdot N_2HPh$, crystallises in pale-yellow needles, and melts at 142° ; the *phenylhydrazonesulphonic acid* forms yellow or reddish crystals, and melts at 268° .

By the action of sodium amalgam, the ketone yields a mixture of two products; one of these separates in crystalline flakes, which increase in quantity on the addition of water, and may be recrystallised from alcohol. It consists of the *pinacone of ethyl α -pyridyl ketone*, $C_5Et_2(C_5NH_4)_2(OH)_2$; this forms white needles, melts at 135 — 136° , and yields a *platinochloride*, $C_{15}H_{20}N_2O_2 \cdot H_2PtCl_6 + H_2O$, which readily loses its water of crystallisation. The filtrate from the pinacone, after further treatment with sodium amalgam at 30 — 40° ,

yields the second product of the reduction, which may be extracted with ether, and consists of *α-ethylpyridylalkine*, $C_8NH_4 \cdot CHEt \cdot OH$; it is a thick, yellowish oil which boils at 213—216°, very readily undergoes oxidation in the air, and forms a *platinochloride*,

crystallising in yellow prisms.

Different results are obtained by reducing the ketone with sodium in amyl alcohol solution. The fractions of the crude product boiling between 190—250° all solidify more or less on cooling, and the solid compound, after freeing from adhering oil and recrystallising from light petroleum, forms white needles which melt after sublimation at 99—100°; it has the composition $C_8H_{17}NO$, and from its mode of preparation must be *α-ethylpiperylalkine*, $C_8NH_{10} \cdot CHEt \cdot OH$. It has in all its properties the strongest possible resemblance to the *pseudoconhydrine* obtained by Merck from *Conium maculatum*, and further examined by Ladenburg and Adam (this vol., p. 1119). There is indeed a difference of 2° in the melting point, but this may be due to the fact that the synthetical compound is an optically inactive variety. On further reduction, it is converted into comine.

The light petroleum mother liquors from *α-ethylpiperylalkine* contain another crystalline substance which melts at 68—69°, and is being further examined.
H. G. C.

Propyl *α*-Pyridyl Ketone. By C. ENGLER and H. MAJMON (*Ber.*, 24, 2536—2538).—*Propyl α-pyridyl ketone*, $C_8NH_4 \cdot COPr^a$, is obtained by distilling a mixture of calcium picolinate and butyrate, and is a colourless liquid, which boils at 216—220°, does not solidify at −20°, and assumes a greenish colour on exposure to air. Its salts are mostly deliquescent; the *platinochloride* forms yellow, crystalline plates almost insoluble in water and alcohol, the *mercuriochloride* melts at about 78°, the *methiodide* at 79°, and the *chloriodo-additive product* at 85°. The *oxime*, $C_8NH_4 \cdot OPr^a \cdot NOH$, crystallises from light petroleum in long, white needles, melts at 48°, and yields a *benzoyl* derivative melting at 56—57° (uncorr.). The *phenylhydrazone* forms yellowish-white, lustrous needles, and melts at 82°, and the *phenylhydrazonesulphonic acid* beautiful, yellow needles melting at 251° (uncorr.).

Sodium amalgam readily acts on the ketone, and yields a mixture of the *pinacone*, $C_{13}H_{24}N_2O_2$, and of *α-propylpyridylalkine*,

The former crystallises from alcohol in white, lustrous needles, and melts at 146° (uncorr.); the latter was only obtained in small quantity, and is an oil, the boiling point of which lies between 212° and 224°.
H. G. C.

***β*-Ketone Derivatives of Pyridine.** By C. ENGLER (*Ber.*, 24, 2539—2542).—*Ethyl β-pyridyl ketone*, $C_8NH_4 \cdot COEt$, is prepared by distilling a mixture of calcium nicotinate with a slight excess of calcium propionate. It is isolated from the crude distillate by means of phenylhydrazine, the hydrazone being decomposed by boiling hydrochloric acid, the precipitated hydrochloride filtered off, and the re-

maining phenylhydrazine destroyed by the careful addition of potassium nitrite. The liquid is then saturated with alkali, extracted with ether, the ethereal solution evaporated, and subjected to fractional distillation. The ketone is thus obtained as a pale-yellow liquid which boils at 230—232°, and darkens on remaining in the air. The *platinochloride* forms golden-yellow crystals, and the *picrate* yellow needles; the *mercurochloride*, $C_8H_5NO \cdot HgCl_2$, may be crystallised from a dilute mercuric chloride solution, and melts at 130°. The *oxime*, $C_8NH_4 \cdot CEt \cdot NOH$, crystallises in white needles, and melts at 115°; the *hydrazone*, $C_8NH_4 \cdot CEt \cdot N_2HPh$, in yellow needles melting at 145° (uncorr.), and the *hydrazonesulphonic acid* in pale-yellow needles melting at 235° (uncorr.).

Propyl β-pyridyl ketone, $C_8NH_4 \cdot COPr^a$, is obtained in a similar manner from calcium nicotinate and butyrate, and is an almost colourless liquid boiling at 246—252°, the odour of which resembles that of coniine. The *hydrazone* melts at 182°, the *hydrazonesulphonic acid* at 283°, the *mercurochloride* at 173°, and the *ethiodide* at 192°. The *picrate* and *platinochloride* also crystallise well, and the *oxime* forms a white, crystalline powder.

H. G. C.

Behaviour of "Dimethylpiperidine" and Allied Bases towards Hydrogen Chloride. By G. MERLING (*Annalen*, 264, 310—351).—The tertiary base obtained by Hofmann (*Ber.*, 14, 659) by the dry distillation of dimethylpiperidylammonium hydroxide, and named by him dimethylpiperidine, is an unsaturated compound of the constitution $CH_2 \cdot CH \cdot [CH_2]_3 \cdot NMe_3$, and is termed by the author butallylcarbindimethylamine (methyl = carbin, methylamine = carb-amine). When this base is heated in a stream of hydrogen chloride, it is converted into methyl-α-methylpyrrolidine, and not into methylpiperidine, as was supposed by Hofmann. The experiments on which these statements are based, and others of a like nature, are described below.

Hydrochlorobutallylcarbindimethylamine, $CHClMe \cdot [CH_2]_3 \cdot NMe_3$, is obtained in the form of its hydrochloride when Hofmann's "dimethylpiperidine" is heated in a stream of hydrogen chloride at 130—160°, and also when "dimethylpiperidine hydrochloride" is treated with an aqueous solution of hydrogen chloride saturated at 0°. This salt is a crystalline substance readily soluble in water; when melted in a stream of dry hydrogen, it gradually loses hydrogen chloride. The free base is a colourless oil. The *aurochloride*, $C_8H_{10}Cl \cdot NMe_3 \cdot HAuCl_4$, crystallises from hot concentrated hydrochloric acid in large, golden plates.

Dimethyl-α-methylpyrrolidylammonium chloride,

is formed when hydrochlorobutallylcarbindimethylamine is heated at 150°, and the product freed from butallylcarbindimethylamine by heating it in a stream of hydrogen; it is a colourless, crystalline, deliquescent compound. The *platinochloride*, $(C_7H_{12}NCl)_2PtCl_4$, crystallises in orange-red octahedra, and is sparingly soluble in water.

The *aurochloride*, $C_7H_{16}NCl \cdot AuCl_3$, is sparingly soluble in water, from which it crystallises in golden needles. The corresponding *ammonium iodide*, $C_7H_{16}NI$, prepared by treating methyl- α -methylpyrrolidine with methyl iodide in methyl alcoholic solution, crystallises from alcohol in small, colourless octahedra and cubes, turns yellow on exposure to light, and is very readily soluble in alcohol.

Methyl- α -methylpyrrolidine, $\begin{matrix} CH_2 \cdot CHMe \\ | \\ CH_2 - CH_2 \end{matrix} > NMe$, is formed with evolution of methyl chloride when the ammonium chloride just described is heated strongly; it is a colourless, basic oil, of sp. gr. 0.799 at 15°; it boils at 96—97°, is miscible with water, and has an odour of piperidine. The *platinochloride*, $(C_6H_{13}N)_2, H_2PtCl_6$, crystallises from hot water in flat, orange-yellow needles or prisms, and melts at about 225° with decomposition. The *aurochloride*, $C_6H_{13}N \cdot HAuCl_4$, is sparingly soluble in cold water, and crystallises from hot water in golden needles melting at 215—217° with decomposition.

Butallylmethylcarbinamine, $CH_3 \cdot CH \cdot CH_2 \cdot CH_2 \cdot CHMe \cdot NH_2$, can be obtained by reducing the hydrazone of allylacetone with sodium amalgam in warm, alcoholic glacial acetic acid solution; it is a colourless, mobile liquid, having an odour of piperidine and a strong alkaline reaction; it is miscible with water, boils at 117—118°, and its sp. gr. is 0.779 at 15°. The *hydrochloride* and the *hydrobromide* are deliquescent, crystalline compounds. The *platinochloride*,

crystallises in yellow needles and is moderately easily soluble in cold water; the *aurochloride* is a yellow, crystalline compound.

Butallylmethylcarbintrimethylammonium iodide,

is obtained when the preceding compound is treated with methyl iodide and methyl alcoholic potash; it crystallises from alcohol in well-defined prisms, and melts at 199—200°. The corresponding *chloride*, prepared by treating the iodide with moist silver chloride, is a hygroscopic, crystalline compound.

Butallylmethylcarbinedimethylamine, $CH_3 \cdot CH \cdot CH_2 \cdot CH_2 \cdot CHMe \cdot NMe_2$, is formed, together with various other products, when the dry ammonium chloride just described is heated at 150—180° in a stream of air; it is a colourless oil of sp. gr. 0.780 at 15°, boils at 138—140°, and has a strong odour recalling that of piperidine. The *platinochloride*, $(C_6H_{11}NMe_2)_2, H_2PtCl_6$, is an orange-yellow, crystalline substance readily soluble in water; the *aurochloride* is also crystalline.

Hydrochlorobutallylmethylcarbinamine hydrochloride,

is formed when hydrogen chloride is passed into butallylmethylcarbinamine heated at 130°; it is a colourless, hygroscopic, crystalline substance. The *platinochloride*, $(C_6H_{14}NCl)_2, H_2PtCl_6$, is a pale-yellow, crystalline compound, and is decomposed by boiling water; the *aurochloride* is also crystalline, but the free base is a colourless oil. When hydrochlorobutallylmethylcarbinamine is heated on the

water-bath, it is converted into $\alpha\alpha_1$ -dimethylpyrrolidine hydrochloride, identical with the compound recently described by Tafel (Abstr., 1888, 1015; 1890, 1000). Dimethyl- $\alpha\alpha_1$ -dimethylpyrrolidylammonium iodide crystallises in transparent cubes and octahedra, and decomposes at about 400° , but without melting (Tafel gives $255-256^\circ$ as the melting point of this compound).

Hydrochlorobutallylmethylcarbindimethylamine hydrochloride,

prepared by passing hydrogen chloride into butallylmethylcarbindimethylamine heated at 130° , is a colourless, hygroscopic, crystalline substance. The *platinochloride*, $(\text{C}_8\text{H}_{12}\text{Cl}\cdot\text{NMe}_2)_2\cdot\text{H}_2\text{PtCl}_6$, is a yellow, crystalline compound; it melts at $91-93^\circ$, and is decomposed by boiling water. The *aurochloride* is a yellow powder melting at $76-77^\circ$. The free base is a colourless oil which, when heated on the water-bath, is readily converted into *dimethyl- $\alpha\alpha_1$ -dimethylpyrrolidylammonium chloride*; on further heating, methyl chloride is evolved and methyl- $\alpha\alpha_1$ -dimethylpyrrolidine, identical with Tafel's trimethylpyrrolidine (*loc. cit.*) is formed.

Dimethyl- α -pipecolylammonium iodide, $\text{C}_8\text{H}_{12}\text{NI}$, is formed when α -pipecoline, prepared by Ladenburg's method, is treated with methyl iodide and potash in methyl alcoholic solution; it crystallises from hot alcohol in long, white crystals, and is sparingly soluble in cold alcohol.

Pentallylcarbindimethylamine, $\text{CH}_2\cdot\text{CH}\cdot[\text{CH}_2]_4\cdot\text{NMe}_2$, is obtained when the ammonium iodide just described is treated with moist silver oxide, and the hydroxide thus formed gradually heated to 140° ; it is a colourless oil, of sp. gr. 0.767 at 15° , boils at $143-143.5^\circ$, and has an odour of piperidine; it has a strongly alkaline reaction, and is not miscible with water. The *platinochloride* is an oil, and the *aurochloride* an unstable, crystalline compound.

Hydrochloropentallylcarbindimethylamine hydrochloride,

can be obtained by passing hydrogen chloride into pentallylcarbindimethylamine heated at 160° ; it is a very hygroscopic, crystalline substance. The *platinochloride* and the *aurochloride* are oils.

Methyl- α -pipecoline, $\text{CH}_2\cdot\text{CH}\cdot\left\langle\begin{smallmatrix} \text{CH}_2\cdot\text{CHMe} \\ \text{CH}_2-\text{CH}_2 \end{smallmatrix}\right\rangle\cdot\text{NMe}$, is formed when the preceding compound is decomposed with soda, the colourless, oily base thus obtained heated first at 120° to convert it into dimethyl- α -pipecolylammonium chloride, and then at a higher temperature to eliminate methyl chloride; it can also be obtained by heating dimethyl- α -pipecolylammonium chloride prepared directly from α -pipecoline. It is a colourless oil, of sp. gr. 0.826 at 15° , boils at $126-128^\circ$, and is not miscible with water. The *platinochloride*, $(\text{C}_7\text{H}_{12}\text{N})_2\cdot\text{H}_2\text{PtCl}_6$, separates from hot water in compact, orange-red crystals melting at $180-185^\circ$.

Pentallylcarbintrimethylammonium iodide, $\text{CH}_2\cdot\text{CH}\cdot[\text{CH}_2]_4\cdot\text{NMe}_3\text{I}$, is formed when pentallylcarbindimethylamine is treated with methyl iodide in methyl alcoholic solution; it separates from alcoholic ether

in colourless plates melting at 126—129°; when treated with moist silver oxide, it is converted into a strongly alkaline hydroxide, which is decomposed, on heating at about 160°, into water, trimethylamine, diallyl (b. p. 60—61°), and a hydrocarbon (b. p. 80—83°) isomeric with diallyl.

The *hydrocarbon*, boiling at 80—83°, is a colourless, refractive oil, of sp. gr. 0.727 at 15°, and has an odour like that of diallyl; it combines readily with bromine, yielding a *tetrabromide* $C_6H_{10}Br_4$, which crystallises from hot glacial acetic acid in lustrous plates melting at 160—162°; on oxidation with chromic acid, it yields carbonic anhydride and acetic acid.

When butallylmethylcarbintrimethylammonium iodide (m. p. 199—200°) is digested with moist silver oxide, it is converted into the corresponding hydroxide; this substance decomposes at about 160° into water, trimethylamine, diallyl, and a hydrocarbon (b. p. 80—83°) identical with that obtained from pentallylcarbintrimethylammonium iodide in like manner.

F. S. K.

Formation of Bases of the Quinoline Series. By E. LELLMANN and W. LIPPERT (*Ber.*, 24, 2623—2624).—It is known that either aniline or nitrobenzene yields quinoline when heated with glycerol and sulphuric acid, and that in the one case oxidation, in the second reduction, must occur. Azobenzene occupies an intermediate position between aniline and nitrobenzene, and, if found to react with acetaldehyde, might, therefore, be expected to do so without either oxidation or reduction being necessary. This conclusion is confirmed by experiment, since the authors find that azobenzene (compare Claus and Stegelitz, *Abstr.*, 1887, 173) and its derivatives yield bases of the quinoline series when heated with glycerol and sulphuric acid. Azobenzene and parazotoluene give, respectively, quinoline and toluquinoline, whilst amidoazobenzene forms a mixture of quinoline and pseudophenanthroline. The yield in each case was small.

W. P. W.

Preparation of Amidoquinoline. By J. EFRAIM (*Ber.*, 24, 2817—2820).— *α -Phenylhydrazoquinoline*, $C_6NH_4 \cdot NH \cdot NHPH$, is prepared by carefully heating a mixture of *α -chloroquinoline* (1 mol.) and phenylhydrazine (2 mols.) in a reflux apparatus, over a free flame, extracting the uncombined portion of the reagents, and the phenylhydrazine hydrochloride produced, with boiling water, and crystallising from absolute alcohol. It then separates in white needles, melts at 191° with decomposition, and is readily soluble in glacial acetic acid and chloroform, almost insoluble in ether; it gives a violet colour with concentrated sulphuric acid, which, on diluting with water, becomes rose-coloured. The yield is equal to that of the chloroquinoline employed.

α -Phenylazoquinoline, $C_6NH_4 \cdot N_2Ph$, is formed by oxidising the hydrazo-compound, best as follows:—The hydrazo-derivative is dissolved in glacial acetic acid, an excess of ferric chloride added, and after a while the mixture diluted with water, when the azo-derivative separates in delicate, red needles; it melts at 93°, and is readily soluble

in glacial acetic acid, alcohol, and ether; it exhibits the same colour reaction with concentrated sulphuric acid as the hydrazo-derivative.

α-Amidoquinoline, $C_8NH_6NH_2$ [$NH_2 = 2'$], is obtained by heating *α*-phenylhydrazoquinoline (1 gram) with hydriodic acid (1.7 grams) and amorphous phosphorus (0.5 gram) in a sealed tube at 180° for an hour, rendering the product alkaline, driving over the aniline with a current of steam, and extracting the residual solution with ether, from which the new base is obtained as a violet, crystalline mass, which, when crystallised from light petroleum, melts at 114° , and is readily soluble in alcohol, ether, chloroform, and benzene; the *picrate* and the *platinochloride* are sparingly soluble compounds. A *hydrazo-derivative* melting at 197° is obtained from *α*-chlorolepidine.

A. R. L.

Tetrahydro-derivatives of β -Naphthaquinoline and β -Naphthaquinaldine. By E. BAMBERGER and R. MÜLLER (*Ber.*, 24, 2641—2647).— β -Naphthaquinoline (Skraup and Cobenzl, *Abstr.*, 1883, 1010) is most readily purified by pouring the product of the Skraup reaction into water, neutralising partially with caustic soda, filtering from tarry matters, and, with the object of removing all resinous matters from solution, heating the filtrate on a water-bath with sodium nitrite until it gives the reactions of nitrous acid. The pure base separates in the solid form on the addition of excess of alkali to the filtrate. It boils at 349.5 — 350° (thermometer in vapour) under 721 mm. pressure.

Tetrahydro-β-naphthaquinoline, $C_{12}H_{12}N$, is obtained when β -naphthaquinoline (20 grams), dissolved in concentrated hydrochloric acid, is gradually added to a boiling mixture of tin (80 grams) and hydrochloric acid (500 grams), and heated until the metal is dissolved. The crystalline stannochloride, which separates on cooling, is decomposed by aqueous soda, and the base purified by distillation with steam and subsequent crystallisation from light petroleum. It crystallises in lustrous, silvery-white needles or scales, melts at 93.5° , and dissolves readily in the ordinary organic solvents, but only sparingly in water. The solutions in indifferent solvents are destitute of fluorescence, but those in mineral acids show a beautiful blue fluorescence, resembling that of anthracene. Ferric chloride or potassium dichromate, added to the acid solution, produces a deep, reddish-brown coloration, rapidly changing to dark brown. The *hydrochloride*, $C_{12}H_{12}N.HCl$, crystallises in silvery-white prisms, melts at 230.5 — 231° , and dissolves easily in water, but only sparingly in strong hydrochloric acid; the *sulphate* forms lustrous, white needles, and is very soluble in water. The *acetyl* derivative, $C_{12}H_{12}N.Ac$ [$Ac = 1'$], crystallises in white prisms, melts at 77° , and is sparingly soluble in water, but readily in most other solvents. The *nitroso-derivative*, $C_{12}H_{12}N.NO$, crystallises from alcohol in silvery-white prisms or scales, melts at 105.5° , and dissolves easily in benzene, chloroform, ether, &c.

1''-Benzeneazotetrahydro-β-naphthaquinoline, $C_{13}NH_{12}.N_2Ph$ [$N_2Ph = 1''$], prepared by the action of diazobenzene chloride on tetrahydro- β -naphthaquinoline in the presence of sodium acetate, crystallises from light petroleum in yellow needles of golden lustre, melts at 96.5 — 97° , and dissolves easily in the ordinary organic solvents.

When warmed with mineral acids, it decomposes into the tetrahydro-base, phenol, and nitrogen.

Tetrahydro-β-naphthaquinaldine is obtained by reducing β-naphthaquinaldine by the method just described. It crystallises from light petroleum in hard, thick, glassy prisms, melts at 51·5—52°, dissolves readily in the ordinary organic solvents, but only sparingly in water, forming fluorescent solutions which lose their blue fluorescence on the addition of a mineral acid. Ferric chloride or potassium dichromate added to an acid solution produces a reddish-brown coloration, which becomes brighter and eventually greenish-yellow when the mixture is warmed. The *hydrochloride*, $C_{14}NH_{13} \cdot HCl$, crystallises in white prisms, melts at 239—240°, and is readily soluble in water, but sparingly in hydrochloric acid. The *acetyl* derivative, $C_{14}H_{13}N \cdot Ac$, forms white needles, melts at 86—86·5°, and dissolves easily in organic solvents. The *nitroso*-derivative, $C_{14}NH_{13} \cdot NO$ [$NO = 1$ "], crystallises from alcohol in straw-yellow, lustrous scales, and melts at 69—69·5°. The *benzeneazo*-compound has not yet been obtained in crystalline form.

W. P. W.

Octohydro-derivatives of β-Naphthaquinoline. By E. BAMBERGER and R. MÜLLER (*Ber.*, 24, 2648—2661).—The first part of this paper is devoted to a restatement of the effect of reduction on the properties of β-naphthaquinoline, for which a previous paper may be consulted (*Abstr.*, 1890, 1303). When β-naphthaquinoline (10 grams) is reduced with sodium (30 grams) and amyl alcohol (250 grams) in the usual way, a mixture of the "alicyclic" and "aromatic" octohydrides is obtained. The relative proportion of the two bases varies slightly in different experiments, but the "aromatic" derivative is always the chief product, the average yield of the "alicyclic" base being about 3 per cent. of the naphthaquinoline employed. To separate the bases, the fluorescent amyl alcohol layer is acidified, the alcohol removed by steam distillation, the residue rendered alkaline, and the bases distilled with steam. The solid distillate is extracted with light petroleum to free it from a very small quantity of a third base insoluble in that solvent, and the "alicyclic" constituent separated as carbonate by treating the filtrate with moist carbonic anhydride. The carbonate is freed from small quantities of the "aromatic" base, which adhere to it even after washing with light petroleum, either by repeating the precipitation with carbonic anhydride several times, or by adding nitrous acid to the cold dilute aqueous solution and extracting the resulting "aromatic" nitrosamine with ether.

ac.-Octohydro-β-naphthaquinoline, $C_{13}NH_{17}$, crystallises from dilute aqueous soda in long, silky, matted needles, or from alcohol in long, glassy prisms, melts at 91°, boils at 321° under 727 mm. pressure, has a basic odour, and is volatile with steam. It gives no colour reactions with ferric chloride, potassium dichromate, or diazotised bases, and in its properties resembles the "alicyclic" tetrahydronaphthylamines; its physiological action, for example, being, according to Filehne, very similar to that of those bases (compare *Abstr.*, 1889, 737), and in no sense like that of quinoline. The *hydrochloride*, $C_{13}NH_{17} \cdot HCl$, crystallises in thick, glassy, monoclinic prisms, melts at 252°, and is readily soluble in water and alcohol, but only sparingly in hydrochloric

acid; the *platinochloride* crystallises in golden-yellow, serrated, thin prisms, melts at 250° with blackening, and dissolves very sparingly in cold water: the *nitrate* forms lustrous prisms, somewhat sparingly soluble in cold water; the *nitrite* crystallises from water in short, thick, glassy prisms, melts at 238° , and is not decomposed by boiling water or cold mineral acids. The *acetyl* derivative, $C_{13}H_{18}NAc$, crystallises from light petroleum in strongly refractive, glassy prisms, from water in small needles, and dissolves readily in the ordinary solvents. The *benzeneazo*-compound, $C_{13}NH_{16}\cdot N_2Ph$ [$N_2Ph = 1''$], obtained by the action of diazobenzene chloride on the base in the presence of sodium acetate, crystallises from aqueous alcohol in silvery-white, flat needles, melts at 95° , is readily soluble in the ordinary organic solvents, and yields a *picrate*, $C_{13}H_{21}N_3\cdot C_6H_3(NO_2)_3\cdot OH$, crystallising in lustrous, golden-yellow needles. The *nitroso*-derivative, $C_{13}NH_{16}\cdot NO$, prepared by heating a solution of the base in excess of acid with the calculated quantity of sodium nitrite at 110 – 120° for 5 hours, crystallises from alcohol in lustrous, flat, serrated, silvery-white prisms, melts at 122.5° , and dissolves readily in ether, chloroform, benzene, and boiling alcohol.

ar.-Octohydro- β -naphthaquinoline, $C_{13}NH_{13}$, exhibits a remarkable power of crystallisation. From its solution in light petroleum, it usually separates in large, transparent, colourless prisms, whose length seems to be conditioned only by the size of the containing vessel. If, however, the concentrated solution is slowly cooled, it forms pale yellow, shorter prisms an inch in thickness, belonging either to the monoclinic, or more probably, the triclinic system; exact crystallographic measurements could not be made, since the crystals, on removal from the solvent, became white and opaque in a few seconds, owing to volatilisation of the light petroleum crystallised with the base. The mother liquor of these efflorescent crystals solidifies after a few minutes to a mass of long, thin, silky needles, which do not alter on exposure to the air. The base melts at 60.5° , boils at 325° under 727 mm. pressure, has a neutral reaction, and dissolves easily in organic solvents, but only sparingly in water. In its reactions, it resembles the "aromatic" tetrahydronaphthylamines; thus it reduces alcoholic silver nitrate in the cold and platinic chloride on warming, reacts with diazotised sulphanilic acid forming a dark claret colouring matter, and gives a yellowish coloration on warming its acid solution with ferric chloride or potassium dichromate. The *hydrochloride*, $C_{13}NH_{17}\cdot HCl$, crystallises either in silvery-white scales or long, glassy prisms, melts at 219° , and is soluble in alcohol and chloroform. The *platinochloride*, $(C_{13}NH_{17})_2\cdot H_2PtCl_6 + 2H_2O$, forms bright-yellow, lustrous scales, melts at 178° , and on warming becomes black, owing to the separation of platinum. The *acetyl* derivative, $C_{13}NH_{16}\cdot Ac$, crystallises in scales or flat, silvery-white prisms, melts at 68.5 – 69° , and dissolves readily in most solvents, but only sparingly in water. The *nitroso*-derivative, $C_{13}NH_{16}\cdot NO$ [$NO = 1''$], crystallises by very slow evaporation of its alcoholic solution in short, thick, glassy, monoclinic prisms, $a:b:c = 2.4245:1:2.75495$; $\beta = 85^{\circ}$, observed forms $0P$, ∞P_{∞} , $-P$, $+P$, and $+2P_{\infty}$. It melts at 106° .

W. P. W.

Octohydro-derivatives of β -Naphthaquinaldine. By E. BAWBERGER and L. STRASSER (*Ber.*, 24, 2662—2669).— β -Naphthaquinaldine (12 grams), on reduction with sodium (32 grams) and boiling amyl alcohol (350 grams), yields a mixture of an "aromatic" octohydro- β -naphthaquinaldine with a very small quantity of "alicyclic" octohydro- β -naphthaquinaldine. These bases can be separated by the method described in the preceding abstract.

ar-Octohydro- β -naphthaquinaldine, $C_{14}NH_{18}$, crystallises from light petroleum in colourless, glassy prisms, from dilute alcohol in glistening scales, melts at 75° , volatilises slowly with steam, and dissolves readily in alcohol, benzene, chloroform, &c., but only sparingly in water. It exhibits reducing properties, and on the addition of silver nitrate to its alcoholic solution, gives first a blue colour and then a separation of metallic silver. Ferric chloride added to the warm aqueous solution of its hydrochloride produces a yellow colour which eventually changes to reddish-brown, with the separation of reddish-brown flocks. The *hydrochloride*, $C_{14}NH_{18}HCl$, crystallises in white, lustrous, feathery crystals, melts at 210° , and dissolves readily in alcohol, but only sparingly in hydrochloric acid. On the addition of platonic chloride to its aqueous solution, yellow needles of a platino-chloride are obtained, which become black on heating the solution, owing to a separation of platinum. The *nitrate*, $C_{14}NH_{18}HNO_3$, crystallises in lustrous, white needles, melts at 170° , and is easily soluble in water and dilute nitric acid on boiling, but only sparingly in the cold. The *acetyl* derivative, $C_{14}NH_{18}Ac$ [$Ac = 1''$], crystallises from light petroleum in aggregates of lustrous needles, melts at 92° , and dissolves readily in most solvents, but only sparingly in water. The *nitroso*-derivative, $C_{14}NH_{18}NO$, forms straw-yellow, lustrous needles, melts at 86° , and is easily soluble in ether, benzene, chloroform, and boiling alcohol.

1''-Benzeneazo-*ar*-octohydro- β -naphthaquinaldine, $C_{14}NH_{18}N_2Ph$ [$N_2Ph = 1''$], is obtained when a solution of octohydro- β -naphthaquinaldine and sodium acetate in aqueous alcohol is treated with the calculated quantity of diazobenzene chloride. By slow evaporation of its solution in light petroleum, it crystallises in pale-yellow, glassy, thick, rhombic prisms, $a : b : c = 0.8037 : 1 : 0.5600$, forms observed $2P_\infty$ and P , melts at 97.5 — 98° , and is extremely soluble in ether, chloroform, and benzene. When boiled with mineral acids, it decomposes in the normal way into octohydro- β -naphthaquinoline, phenol, and nitrogen; as anticipated, however, it does not undergo intramolecular change into the azo-compound on treatment of its alcoholic solution with hydrochloric acid, since the para-position is not open in the central ring, which by hydrogenation of the lateral rings has acquired properties identical with those of benzene.

2'-Benzeneazo-*ar*-octohydro- β -naphthaquinaldine, $C_{14}NH_{18}N_2Ph$ [$N_2Ph = 2'$], is formed when a cooled dilute alcoholic solution of the hydrochloride of the base is treated with diazobenzene nitrate. It crystallises from alcohol in dark, ruby-red prisms of greenish, bronze-like lustre, and dissolves readily in alcohol, ether, chloroform, &c., but only sparingly in water. The alcoholic solution is raspberry-red in colour, but, on the addition of a drop of concentrated hydrochloric

acid, becomes emerald-green. Concentrated sulphuric acid dissolves it, forming a raspberry-red solution, which, on adding a little water, becomes emerald-green, and on further dilution, becomes rose-coloured and seemingly fluorescent, owing to the precipitation of the colouring matter. *Sulphobenzeneazo-ar.-octohydro-β-naphthaquinoline* is a greenish-black, crystalline powder which dissolves in alcohol and water with a deep-red colour, and in alkalis forming dark claret solutions.

Orthamido-ar.-octohydro-β-naphthaquinaldine [$\text{NH}_2 = 2'$] is prepared by boiling the alkaline solution of the sulphobenzeneazo-derivative with zinc dust until the colour becomes bright-yellow, and subsequently extracting with ether. It exhibits the reactions of an orthodiamido-derivative of benzene on treatment with dilute solutions of ferric chloride or potassium dichromate, and on boiling with acetic acid is converted into *α-methyl-ar.-octohydro-β-naphthaquinaldimidazole*. The imidazole hydrochloride crystallises from alcohol or ether-alcohol in glassy prisms, melts at 262° with decomposition, dissolves readily in acids, and gives no colour reactions with ferric chloride or potassium dichromate.

ac.-Octohydro-β-naphthaquinaldine, $\text{C}_{14}\text{NH}_{10}$, crystallises in long, silky needles, dissolves easily in the ordinary organic solvents, but only sparingly in water, has a strongly alkaline reaction, and volatilises readily with steam. It is destitute of reducing powers, and exhibits the properties of an "alicyclic" base. The *hydrochloride* crystallises in silvery scales, and dissolves readily in water, but only sparingly in hydrochloric acid; the *platinochloride* forms orange-red, flat needles.

W. P. W.

A New Class of Fluorescent Colouring Matters of the Quinoxaline Series. By O. FISCHER and M. BUSCH (*Ber.*, 24, 2679—2683).—An azonium base identical with the compound (m. p. 167°) obtained by oxidising triphenyletho- $\alpha\beta$ -hydronaphthaquinoxaline (this vol., p. 1109) is formed when benzile is treated with phenylorthonaphthylendiamine as described by Witt (*Abstr.*, 1887, 729).

1:3-Diphenyletho- $\alpha\beta$ -dihydronaphthaquinoxaline,

is formed, together with a very small quantity of a dark-red substance described below, when benzoylcarbinol, prepared by hydrolysing acetylacetophenone with barium carbonate, is heated with phenylorthonaphthylendiamine at 150 — 160° in sealed tubes for 4—5 hours. The crude product is dissolved in a mixture of benzene (1 part) and alcohol (3 parts), from which, on keeping for a long time, the quinoxaline is deposited in compact, orange-red needles. It melts at 164 — 165° , and is readily soluble in benzene, but more sparingly in ether and glacial acetic acid, very sparingly in alcohol, and almost insoluble in light petroleum; its solutions show an intense yellowish-green fluorescence. It dissolves in concentrated sulphuric acid and in concentrated hydrochloric acid, yielding a dark brownish-red solution, from which it is reprecipitated in a yellow, flocculent condition on the addition of water. On oxidation with

ferric chloride, it is converted almost quantitatively into diphenyletho-naphthazonium hydroxide, identical with the compound previously described (*loc. cit.*).

The dark-red bye-product mentioned above is obtained in crystals when the alcoholic benzene mother liquors from the quinoxaline base are mixed with ether and then slowly evaporated; it is soluble in benzene and ether, but only sparingly in alcohol and light petroleum, its solutions showing a beautiful purple-red fluorescence; it melts at about 194–196°, and forms a stable salt with sulphuric acid.

n-Methyldiphenyldihydroquinoxaline, $C_6H_4 \begin{matrix} NMe \cdot NPh \\ \diagup \quad \diagdown \\ N = CPh \end{matrix}$, is

formed when benzoin is heated with methylorthophenylenediamine at 160–170° for 5–6 hours; it crystallises from alcohol in concentrically-grouped, yellow needles, melts at 133°, and is readily soluble in benzene and ether, but only moderately easily in alcohol, and very sparingly in light petroleum; its solutions show a greenish-yellow fluorescence. It is a feeble base, its salts being partially decomposed by water; it dissolves in concentrated sulphuric acid, yielding a yellow solution, which first changes to red and then becomes yellow again on the addition of water. When the quinoxaline is heated with ferric chloride and hydrochloric acid in alcoholic solution, it is converted into an ammonium base, the ferrichloride of which crystallises in long, yellow prisms. F. S. K.

Nitroso-derivatives of the Thiazoles. By E. NAF (*Annalen*, 265, 108–128).—Diazothiazole hydrate, $\begin{matrix} CH \cdot S \\ || \\ CH \cdot N \end{matrix} > C \cdot N \cdot N \cdot OH$, or μ -

nitrosoimidothiazoline, $\begin{matrix} CH - S \\ || \\ CH \cdot NH \end{matrix} > C \cdot N \cdot NO$, can be obtained in a slightly impure condition, by gradually adding a well-cooled, concentrated solution of sodium nitrite to a concentrated aqueous solution of amidothiazole nitrate cooled to –10°; the amorphous, orange-red, flocculent precipitate is quickly separated by filtration at a low temperature and dried in a desiccator. It is very unstable when moist, and even in the dry state it gradually turns black; when quickly heated, it decomposes at about 140° with explosion. It is soluble in alcohol and ether, but insoluble in water; its conversion into chloro- and bromo-thiazole has been previously described by Schatzmann (this vol., p. 744).

μ -Imido-*n*-methylthiazoline, $\begin{matrix} CH - S \\ || \\ CH \cdot NMe \end{matrix} > C \cdot NH$, is formed when amidothiazole is heated with methyl iodide in methyl alcoholic solution at 130° for several hours, and the hydriodide obtained in this way decomposed with potash; it is a yellowish-brown, very hygroscopic, strongly alkaline liquid. The *hydriodide*, $C_2H_5N_2S \cdot HI$, crystallises in colourless plates, and melts at 175°. The *hydrochloride* crystallises from water, in which it is very readily soluble, in large plates, and melts at 97°; the *platinochloride* is sparingly soluble.

n-Methylimidothiazoline, $\begin{matrix} CH - S \\ || \\ CH \cdot NH \end{matrix} > C \cdot NMe$, is produced when an

aqueous solution of methylthiocarbamide is warmed with dichloro-ether; it is a yellowish-brown oil, which, on keeping, gradually solidifies to a mass of very hygroscopic crystals. The *hydrochloride*, $C_4H_4N_2S.HCl$, is a semi-crystalline, hygroscopic compound melting at $79-80^\circ$. The *platinochloride* crystallises in long needles.

Dimethylimidothiazoline, $\begin{array}{c} CH-S \\ || \\ CH \cdot NMe \end{array} > C:NMe$, can be obtained by methylating either of the bases just described, but more conveniently by warming an aqueous solution of dimethylthiocarbamide with dichloroether; it is a hygroscopic liquid.

The *hydrochloride*, $C_5H_5N_2S.HCl$, crystallises well, and melts at 222° .

μ -*Nitroso-n-methylimidothiazoline*, $\begin{array}{c} CH-S \\ || \\ CH \cdot NMe \end{array} > C:N \cdot NO$, is precipitated in yellow, lustrous plates when a concentrated solution of sodium nitrite is added to a solution of μ -imidomethylthiazoline hydrochloride in well-cooled, very dilute hydrochloric acid; it melts at 161° with a slight explosion, and is soluble in alcohol and ether, but only sparingly in water. The dry compound is stable, and dissolves unchanged in alkalis, but when treated with concentrated mineral acids, or with powerful reducing agents, it is reconverted into μ -imidomethylthiazoline.

n-Methylthiazolinehydrazine, $\begin{array}{c} CH-S \\ || \\ CH \cdot NMe \end{array} > C:N \cdot NH_2$, is formed in small quantities when an alcoholic solution of the preceding compound is mixed with excess of zinc-dust, and acetic acid gradually added to the well-cooled mixture; it is a yellow, disagreeably smelling oil. The *hydrochloride*, $C_4H_7N_3S.HCl$, and the sparingly soluble *picrate* crystallise in yellow needles.

n-Nitroso- μ -methylimidothiazoline, $\begin{array}{c} CH-S \\ || \\ CH \cdot N(NO) \end{array} > C:NMe$, can be obtained by treating μ -methylimidothiazoline with nitrous acid under the conditions given above; it forms small, yellowish crystals, has a characteristic odour recalling that of acetamide, and is much more unstable than the isomeride described above, being converted into resinous products on keeping in a dry condition, or on boiling with water or alcohol. It turns black when slowly heated, and melts at about 140° , but when heated quickly it explodes at about $110-120^\circ$; it is freely soluble in alkalis and in ammonia, by which it is completely decomposed. The corresponding hydrazine could not be obtained.

The hydrochloride of a base which the author names *thiazoletriazole*, $CH < \begin{array}{c} S-C:N \\ | \\ CH \cdot N \cdot N \end{array} > CH$, is formed when freshly prepared *n*-nitroso- μ -methylimidothiazoline is dissolved in well-cooled 10 per cent. hydrochloric acid, and the solution warmed until no further evolution of gas takes place; on keeping for some time, the *hydrochloride*,

is deposited in needles, which turn brown and lose their water at 130—140°. and melt at 210—220°. The *hydrobromide*,

forms long, prismatic crystals, turns brown on keeping, loses its water at 130—140°, and decomposes completely at a higher temperature, but without melting. The free base is a brown oil, which gradually solidifies to a vitreous mass; it is very readily soluble in water, has an alkaline reaction, and reduces Fehling's solution; when its hydrochloride is treated with sodium nitrite in aqueous solution, a large quantity of *n*-nitroso- μ -methylimidothiazoline is formed.

μ -Phenylimidothiazoline, $C_9H_8N_2S$, prepared by treating dichlorether with phenylthiocarbamide and decomposing with potash the salt produced, crystallises from alcohol, ether, and benzene in small, colourless needles, and melts at 124°; its salts are not easily obtained in crystals.

Diphenylimidothiazoline, $C_{18}H_{12}N_2S$, obtained from diphenylcarbamide in like manner, is a granular, crystalline substance melting at 105°.

μ -Phenyl-*n*-nitrosoimidothiazoline, $C_9H_7N_3SO$, is precipitated in the form of a microscopic, crystalline powder on treating μ -phenylimidothiazoline with sodium nitrite in well-cooled, dilute hydrochloric acid solution; it forms yellow crystals, melts at 58°, and decomposes on keeping. It is insoluble in alkalis, and, when treated with acids, it is reconverted into μ -phenylimidothiazoline.

F. S. K.

Action of Hydriodic Acid on Quinine and Cinchonine. By E. LIPPMANN and F. FLEISSNER (*Ber.*, 24, 2827—2829).—The action of hydriodic acid on quinine is similar to that of hydrochloric or hydrobromic acid on the base (*Monatsh.*, 12), and leads to the formation of hydriodoquinine hydriodide, $C_{20}H_{24}N_2O_2.3HI$, which, on treatment with ammonia, yielded hydriodoquinine, $C_{20}H_{24}N_2O_2.HI$, with the elimination of 2 mols. of hydrogen iodide. When boiled with alcoholic potash, hydriodoquinine is converted into isoquinine. A better yield of this base is obtained by heating hydriodoquinine hydriodide with water at 150—160° for about six hours, adding the pale-yellow solution to aqueous ammonia, extracting with ether, and drying the ethereal solution over caustic potash. After a short time, the sparingly soluble isoquinine crystallises from the solution, and a further quantity can be obtained by evaporation, the ethereal mother liquor containing quinine.

Hydriodocinchonine hydriodide, $C_{19}H_{22}N_2O.3HI$, is formed when cinchonine, free from sulphuric acid, is slowly stirred into warm hydriodic acid (sp. gr. 1.7—1.8), and can be freed from cinchonine hydriodide by washing the crystalline precipitate with alcohol. It crystallises in small, bright-yellow, lustrous prisms, decomposes when heated at 215°, and dissolves sparingly in alcohol and cold water, but easily in hot water. On digestion with warm, dilute aqueous ammonia, it is converted into *hydriodocinchonine*, $C_{19}H_{22}N_2O.HI$, which crystallises in slender, silky needles, melts at 158—160°, dissolves very sparingly in ether, but more easily in alcohol, and yields a

platinochloride of the composition $C_{19}H_{22}N_2OHI + H_2PtCl_6$. Cinchonine is regenerated when hydriodocinchonine hydriodide is heated with water under pressure. W. P. W.

Quinethyline. By E. GRIMAUD and A. ARNAUD (*Compt. rend.*, 112, 1364—1367).—It has been shown in a former communication that quinine is a methyl ether of cupreine; quinethyline is the corresponding ethyl ether. It is prepared from specially purified cupreine as follows:—A molecular proportion of dry cupreine is dissolved in alcohol, to which has been added $1\frac{1}{2}$ mols. of sodium, and heated in sealed tubes, at 95—100° with $1\frac{1}{2}$ mols. of ethyl nitrate for from 12 to 15 hours. The alcohol is distilled off, the residue taken up with acidified water, an excess of soda added, and the new base extracted with ether. The ethereal solution is then shaken with dilute sulphuric acid, the aqueous solution separated from the ether, heated on the water-bath, and carefully neutralised by ammonia. When the concentrated liquor is cooled, strongly coloured basic sulphate of the base separates. The crude product is converted into the normal sulphate, which is purified by heating with animal charcoal and subsequently recrystallising it from boiling water. The base is precipitated from a cold, concentrated solution of the normal sulphate by the addition of a slight excess of ammonia. The precipitate is white and amorphous, much resembling quinine; it consists of hydrates melting at 60°.

The dry, pulverulent base may be obtained by desiccating in dry air, and afterwards heating at 100—120°; it melts at 160°. It is very soluble in all the ordinary solvents for alkaloids, and yields very fluorescent solutions with excess of sulphuric acid. It does not crystallise from alcohol, behaving in exactly the same way as quinine. Large, colourless, transparent crystals of a hydrate may easily be obtained. The base is levorotatory; its solution in absolute alcohol gives $[\alpha]_D = -169.4^\circ$.

The *normal sulphate*, $C_{21}H_{28}N_2O_2 \cdot SO_4H_2 + 8H_2O$, crystallises in large, colourless, eight-sided prisms, efflorescing rapidly in the air. It dissolves in 51 l parts of water at 19°, and is very soluble in boiling water. When heated with the calculated quantities of hydriodic acid and iodine in alcoholic solution, it yields small, garnet-red needles differing from the plates of herapathite given by quinine.

The *basic sulphate*, $(C_{21}H_{28}N_2O_2)_2 \cdot SO_4H_2 + H_2O$, is readily prepared from the normal sulphate by dissolving the latter in boiling water and neutralising exactly with dilute ammonia, using litmus as indicator. It forms crystalline plates of a silky lustre, requiring 397 parts of water for solution at 15°. Its solution in dilute hydrochloric acid gives $[\alpha]_D = -233.1^\circ$. The yield of pure basic sulphate was about 35 parts per 100 of cupreine taken. W. T.

Hydrastine. By M. FREUND and O. DORMEYER (*Ber.*, 24, 2730—

2741).—Hydrohydrastinine, $CH_2 \begin{smallmatrix} \text{O} \\ \diagup \quad \diagdown \\ \text{O} \end{smallmatrix} C_6H_5 \begin{smallmatrix} \text{CH}_2 \cdot NMe \\ \diagup \quad \diagdown \\ \text{CH}_2 \cdot CH_2 \end{smallmatrix}$ (compare

Freund and Will, Abstr., 1887, 383), is best prepared by reducing hydrastrinine with 8 per cent. sodium amalgam in dilute sulphuric acid solution; the yield of crystalline product is 90 per cent. of the base employed.

Hydrohydrastrinine methiodide, $C_{11}H_{13}NO_2 \cdot MeI$, is deposited in colourless crystals when a slight excess of the theoretical quantity of methyl iodide is added to a methyl alcoholic solution of hydrohydrastrinine, and the mixture kept for some time; it crystallises from hot water in needles, and from dilute alcohol in iridescent plates, melts at $227-228^\circ$, and is not acted on by boiling, concentrated potash, or when melted with potash. The *platinochloride*, $(C_{12}H_{15}NO_2Cl)_3 \cdot PtCl_4$, is formed when an aqueous solution of the methiodide is digested with silver chloride, and the filtrate treated with platinic chloride; it crystallises from hot water in well-defined needles, and melts at 230° .

Methylhydrohydrastrinine, $CH_3 \cdot \langle O \rangle \cdot C_6H_5 \cdot \langle \begin{smallmatrix} CH_2 \cdot NMe_2 \\ CH \cdot CH_2 \end{smallmatrix} \rangle$, can be obtained by digesting an aqueous solution of the methiodide just described with silver chloride, and decomposing the product with boiling, concentrated potash; it is an almost colourless, moderately mobile oil, having an amine-like odour, and strong basic properties; it is soluble in ether, alcohol, and carbon bisulphide, and cannot be distilled. The *hydriodide*, $C_{12}H_{15}NO_2 \cdot HI$, is easily obtained by dissolving the base in dilute hydrochloric acid, and adding potassium iodide to the solution; it crystallises from hot water in colourless, lustrous, hexagonal prisms, melts at $220-221^\circ$, and is decomposed by potash. On adding potassium dichromate to a dilute solution of the hydriodide, a golden-yellow substance is precipitated in needles which melt at 150° with decomposition. The *platinochloride*,

separates from hot alcohol and water in ill-defined crystals, and melts at 171° . The *methiodide*, $C_{12}H_{15}NO_2 \cdot MeI$, is formed by the direct combination of the base with methyl iodide in alcoholic solution; it crystallises from hot water in transparent, hexagonal prisms, melts at $216-217^\circ$, and is not decomposed by boiling concentrated alkalis. The *methochloride*, $C_{12}H_{15}NO_2 \cdot MeCl$, is obtained in the form of microscopic, hexagonal prisms when an aqueous solution of the methiodide is digested with silver chloride, and the filtrate evaporated; it crystallises from alcohol in lustrous plates melting at 211° . Its *platinochloride*, $(C_{12}H_{15}NO_2Cl)_3 \cdot PtCl_4$, is an indistinctly crystalline compound which melts at 221° , and is almost insoluble in water; the corresponding *aurochloride*, $C_{12}H_{15}NO_2Cl \cdot AuCl_3$, is a yellow, crystalline, sparingly soluble substance melting at 153° . The *ammonium base*, $C_{12}H_{15}NO_2 \cdot MeOH$, is a strongly alkaline syrup, readily soluble in water.

Bromomethylhydrohydrastrinine, $C_{12}H_{14}NO_2Br$, is obtained when methylhydrohydrastrinine is treated with bromine in carbon bisulphide solution until a permanent coloration is produced, and the brown, semi-solid product agitated with dilute soda. It crystallises from hot water in octahedra, melts at 187° , and is soluble in alcohol.

Bromohydroxymethylhydrohydrastinine methiodide,

is formed when an aqueous solution of methylhydrohydrastinine methochloride is treated with bromine-water until a permanent coloration is produced, and the concentrated solution of the product mixed with potassium iodide; it crystallises from water in colourless prisms melting at 177°.

F. S. K.

Pseudotropine. By O. LIEBERMANN (*Ber.*, 24, 2587).—The author has examined the products of oxidation of pseudotropine. The method employed is the same as that employed for the oxidation of ecgonine and tropine (*Abstr.*, 1890, 1449; this vol., p. 749). The main product is tropic acid. It shows all the properties formerly assigned to this compound, has the same solubility in water and alcohol, has a strongly acid reaction, melts at 251°, and dissolves copper oxide and silver oxide. The silver solution deposits a metallic mirror on warming. The solution of the acid reduces potassium permanganate. The *copper* salt, dried at 125°, has the composition $\text{C}_9\text{H}_9\text{NO}_4\cdot\text{CuOH}$. Together with the above acid, ecgoninic acid is also obtained.

E. C. R.

Alkaloids of the Areca Nut. By E. JAHNS (*Ber.*, 24, 2615—2617; compare this vol., p. 94).—Further investigation has shown that both arecoline and arecaidine exist ready formed in the areca nut, and that the latter is not derived from the former in the process of extraction. Arecaidine and arecaine are most easily separated by treatment with hydrochloric acid and methyl alcohol, since the former is thereby converted into its methyl derivative, arecoline, whilst the latter remains as hydrochloride.

The examination of larger quantities of material has led to the discovery of a fifth alkaloid in areca nut. This has been termed *guvacine*, from *guvaca*, the Indian name for the areca palm. *Guvacine*, $\text{C}_8\text{H}_9\text{NO}_3$, forms small, lustrous, anhydrous crystals, melts at 271—272° with decomposition, and has a neutral reaction. It does not dissolve in ether, chloroform, benzene, or strong alcohol, but is tolerably soluble in water and dilute alcohol, although to a less degree than the other two crystalline alkaloids. The salts crystallise well, have an acid reaction, and resemble the base in their behaviour with the ordinary solvents. The *hydrochloride*, $\text{C}_8\text{H}_9\text{NO}_3\cdot\text{HCl}$, crystallises in broad, flat, anhydrous prisms, and is tolerably soluble in water, but only very sparingly in dilute hydrochloric acid; the *sulphate* forms silvery scales; the *nitrate* crystallises in lustrous prisms. The *platinochloride*, $(\text{C}_8\text{H}_9\text{NO}_3)_2\cdot\text{H}_2\text{PtCl}_6 + 4\text{H}_2\text{O}$, crystallises from water in hexagonal prisms resembling those of the choline derivative, and melts at 211° with frothing and decomposition, whilst the *aurochloride*, $\text{C}_8\text{H}_9\text{NO}_3\cdot\text{HAuCl}_4$, forms broad, flat prisms which melt at about 194—195°. Search is being made for other alkaloids in the areca nut.

W. P. W.

Lupinidine from White Lupines (*Lupinus albus*, Lin.). By G. CAMPANI and S. GRIMALDI (*L'Orosi*, 14, 19—24, and *Gazzetta*, 21, 432—437).—After an historical review of the subject, the authors describe their method of preparing considerable quantities of the extract of lupines, and of separating the alkaloid as platinochloride. This salt has the composition $(C_8H_{15}N)_2 \cdot H_2PtCl_6 + 2H_2O$, as stated by Baumert (*Annalen*, 224, 325). The free alkaloid, *lupinidine*, $C_8H_{15}N$, when freshly prepared, is a pale-yellow, heavy, oily, alkaline liquid, with an extremely bitter and pungent taste; it is freely soluble in water and alcohol, but only sparingly in ether. It hardens on exposure to air, acquiring a yellowish-brown colour. If it is kept for a few days in a sealed tube, groups of white, acicular crystals separate, and gradually increase until the presence of liquid is almost concealed. This is probably due to the presence of a crystallisable hydrated lupinidine, $C_8H_{15}N \cdot H_2O$, side by side with the anhydrous alkaloid. According to Bufalini, 0.5 c.c. of the solution of the hydrochloride causes death in frogs in a couple of hours, symptoms of general paralysis being previously induced. S. B. A. A.

Formation of Carbamide by the Decomposition of Arginine. By E. SCHULZE and A. LIKIERNIK (*Ber.*, 24, 2701—2704).—When arginine (compare Schulze, this vol., p. 857) is boiled with a saturated solution of barium hydroxide, it is decomposed with formation of carbamide; it shows, therefore, a behaviour similar to that of lysatine (compare Drechsel, this vol., p. 95). F. S. K.

Heat-coagulation of Proteïds. By J. CORIN and Q. AUSIAUX (*Bullet. de l'Acad. roy. de Belgique*, 21, 345—361).—In a number of experiments made with ox-serum, the statement made by Halliburton (*J. Physiol.*, 5), that two serum-albumins, separable by fractional heat-coagulation, are present, is confirmed. The temperatures of coagulation found were 73—74° and 79—80° respectively. These temperatures are rather lower than those given by Halliburton, as the true temperature of coagulation is taken as the point when opalescence first occurs. In this last point they agree with Haycraft and Duggan, but differ from them in finding that the concentration of a solution of proteïd has very little influence on the temperature of coagulation; the acidity, however, must be kept constant. W. D. H.

Toxalbumin Secreted by the Microbe of Blennorrhagic Pus. By HUGOUNENQ and ERAUD (*Compt. rend.*, 113, 145—147).—Peptonised beef tea that has served for the cultivation of the micrococcus of blennorrhagic pus, when filtered through porcelain and mixed with excess of alcohol, yields a solid substance, which, when redissolved in water, again filtered through porcelain, and again precipitated by alcohol, yields an amorphous, yellowish-white solid, very soluble in water, and resembling the albuminoids in its chemical and physical properties. It is not coagulated by heat, or by nitric acid, is slowly precipitated by potassium ferrocyanide and acetic acid, but not by magnesium sulphate. It has no diastatic action on starch, sugar, or fibrin, and, when exposed to air in a moist condition, it putrefies

rapidly, with development of a very peculiar odour. It leaves no appreciable residue on incineration, contains phosphorus and 11.45 per cent. of nitrogen, but is free from sulphur. A solution of the toxalbumin sterilised by filtration has no injurious effect when injected under the skin of the dog, and placed on the eye, or in the urethra, but if injected into the testicle it causes suppuration and complete atrophy. No similar effects are produced by the sterilised beef tea or the peptone.

If a solution of asparagine containing meat ashes is used as the cultivation fluid, the microbe develops more slowly, and no toxalbumin is formed. It follows, therefore, that the latter is not simply a secretion of the microbe, but results from its action on the peptone.

C. H. B.

Conversion of Carboxy-hæmoglobin into Methæmoglobin, and Detection of Carbonic Oxide in Blood. By H. BERTIN-SANS and J. MOITESSIER (*Compt. rend.*, 113, 210—211).—The authors find that, contrary to the statements of Weil and of von Anrep, when carboxy-hæmoglobin is mixed with potassium ferricyanide, no compound of carbonic oxide and methæmoglobin is formed, but the product is simply a solution of carbonic oxide in a solution of methæmoglobin, from which it is expelled by the passage of hydrogen or carbonic anhydride, or by being placed in a vacuum, as easily as it is from its solution in water.

In order to detect carbonic oxide in blood, the latter is diluted with twice its volume of water, and mixed with sufficient powdered potassium ferricyanide to ensure complete conversion into methæmoglobin. The flask is then made vacuous, and the gas pumped out is passed into a solution of oxyhæmoglobin contained in a suitable absorption tube. With 400 c.c. of blood, a quantity of carbonic oxide amounting to only one-fifteenth of its volume, can be recognised.

C. H. B.

Physiological Chemistry.

Diastatic Action of Human Saliva. By A. SCHLESINGER (*Virchow's Archiv*, 125, 146—181, and 340—363).—The diastatic activity of saliva was estimated in a number of cases of healthy and diseased persons. The smallest ferment activity was found in a case of diabetes mellitus (0.42 per cent.), and in a case of phthisis (0.45). The other cases of diabetes show a slight diminution, as do also the other cases of phthisis, typhoid, chronic nephritis, mercurial salivation, iodism, articular rheumatism, dyspepsia, cancer, and jaundice. In spinal paralysis, no difference was observed. The eight normal cases showed only slight differences; the greatest difference being 0.097 (0.878 and 0.781). In young children, the ferment activity is rather less than in adults.

The addition of an alcoholic solution of thymol for antiseptic purposes lessened the diastatic activity in one-half of the normal, and one-

third of the pathological cases; in the remaining two-thirds, it did not; the hindering influence is believed to be due both to the thymol and the alcohol, chiefly on the bacteria in the saliva, which appear to be more abundant in pathological than in healthy saliva. A very complete history of the subject and bibliography are given.

W. D. H.

Gelatin as a Reagent for the Detection of Tryptic Enzymes.

By C. FERMI (*Chem. Centr.*, 1891, ii, 87; from *Arch. Hygiene*, 12, 240—260).—In place of fibrin, the author has successfully employed gelatin as a means of detecting the presence of proteolytic enzymes. The gelatin is prepared from 5—10 grams of pure gelatin, and 93 grams of aqueous thymol or phenol solution; 5—10 c.c. of this gelatin is run into a test-tube, allowed to solidify, and the solution under examination, to which a little thymol or phenol has been added, is run on to the surface. If at the end of five or six days the gelatin shows no signs of liquefying, the absence of enzymes is established. By means of this reagent placed in graduated cylinders, the author has been enabled to study the properties of the unorganised ferments, and their behaviour with animal and vegetable tissues.

J. W. L.

Neutral Sulphur and Metabolism. By RUDENKO (*Virchow's Archiv*, 125, 102—114).—In addition to the sulphur present in the urine as sulphates (preformed and ethereal), there is an organic substance or substances, which contain the so-called non-oxidised or neutral sulphur. The amount of this present varies considerably, and a quantity of it was prepared from dogs' urine. The following general conclusions from experiments and observations in cases of disease are given:—

(1.) Many processes which increase the decomposition of the body proteids do not raise also the power of oxidation, but lessen it. This is indicated by the lactic acid which appears in the urine in phosphorus poisoning, the sugar in carbonic oxide poisoning, and the sarcosolactic acid that occurs in the urine during artificial dyspnoea (Hoppe-Seyler) comes under the same category.

(2.) In certain circumstances, not well explicable, the neutral sulphur administered to dogs undergoes complete oxidation in the body; but the separation from the organism takes much longer than if the same element were given combined as sulphuric acid.

W. D. H.

Influence of Sulphonal on Protein Metabolism. By M. HAHN (*Virchow's Archiv*, 125, 182—188).—Several observers having shown that certain narcotics increase nitrogenous metabolism, it was considered advisable to investigate the question so far as it relates to sulphonal. A series of observations were made on a dog, for periods without, and for periods with, the administration of the drug, in addition to the food. The body weight, the nitrogen ingested and excreted, the sp. gr. and amount of the urine, and the sodium chloride in it, are given in tabular form. The periods during which sulphonal was given were two in number. The first produced an increased output of nitrogen, which lasted for a week or

more after the drug was stopped. In the second experiment, the excretion of nitrogen was somewhat diminished, but there was a good deal of diarrhoea, which increased the difficulties of the experiment, which therefore demands repetition. In both cases the output of sodium chloride was increased. W. D. H.

Tissue Fibrinogens. By A. E. WRIGHT (*Brit. Med. Journ.*, ii, 1891, 641—644).—Wooldridge's "tissue fibrinogens" were prepared from testis and thymus by precipitating them from an aqueous extract of the organs by means of acetic acid. They were found to give the biuret reaction, and the nitric acid test for proteoses, but the opinion is expressed that they are not proteoses, but substances from which proteoses are readily formed. Further investigation showed that they were nucleo-albumins. The question whether injection of solutions of tissue fibrinogens acts protectively against the *Bacillus anthracis* was tested on rabbits. The results are inconstant, but tend to show that there is a certain amount of immunity produced.

W. D. H.

Decomposition of Albumin in Fasting. By I. MUNK (*Bied. Centr.*, 20, 521—522; from *Cent. Med. Wiss.*, 27, 833—836).—In opposition to Klemperer's view that the value for the loss of nitrogen (average 11.3 grams a day) obtained in the fasting experiment made on Cetti by Senator, Zuntz, and others was high owing to tuberculosis the author obtained exactly the same mean result in an experiment with a perfectly healthy man who fasted for six days. Voit obtained the same result in a series of experiments with young men. Finally Succi, during a fast of 10 days, lost an average daily amount of 10.7 grams of nitrogen. The chief factors which determine the loss of nitrogen are the small amount of fat in the body and the large amount of water consumed. It was observed that on the two days following the fast, when albumin (101 grams), fat (139 grams), and carbohydrates (309 grams) were given, only 54 grams of albumin was decomposed and quite 40 grams deposited; owing to the consumption of non-nitrogenous matter, the loss of nitrogen was reduced to 8.3 grams.

N. H. M.

Influence of Increased Muscle Activity on the Decomposition of Albumin. By F. HIRSCHELL (*Bied. Centr.*, 20, 519—520; from *Cent. Med. Wiss.*, 29, 66—67).—The author, in experiments made on himself, estimated the daily nitrogen secretions, first, with a mixed diet containing albumin (162 grams), fat (167 grams), and carbohydrates (327 grams); and then with a diet containing albumin (37—43 grams), fat (164—183 grams), and carbohydrates (379—408 grams). The increased muscle activity consisted in doing hard work for six hours daily, and in ascending 400—500 metres. With sufficient food, it was found that the decomposition of albumin was not increased, whether the food contained much or little albumin. If, however, the food is insufficient, a considerable loss of albumin takes place. During three days of rest the author lost 1.5, 2.1, and 4.6 grams of nitrogen, and during three days, on which he worked, 2.1, 5.1, and 6 grams of nitrogen. The results explain those of Argutinsky,

who found the amount of albumin decomposed after muscular exertion to be increased when the feeding was insufficient. N. H. M.

Importance of Asparagine for Feeding. By J. KÖNIG (*Bied. Centr.*, 20, 515—516; from *Centr. Med. Wiss.*, 28, 849—852).—After Pfeiffer and Schulze showed that in germinating plants, asparagine is formed from decomposing reserve albumin, that the asparagine remains as such in air free from carbonic anhydride, whilst in presence of carbonic anhydride it disappears, probably again yielding albumin, it seemed likely that asparagine might in the animal organism be re-generated into albumin when a food is used which is poor in nitrogen but rich in carbohydrates; or at least, that it might economise albumin. The experiments of Weiske, Kennepohl, Schulze, and others with rabbits, fowls, geese, sheep, and cows supported this view, showing that asparagine gives rise to deposition of albumin and to increased milk production. On the other hand, Munk found that in the case of a dog fed exclusively with meat, or with a mixture of meat and carbohydrates, there was no diminution, but rather a slight increase, in the amount of albumin lost. Knieriem, who also experimented with a dog, found no increase in the amount of urine when asparagine was given. v. Voit and Politis, in experiments with rats, found that asparagine did not give rise to any saving of albumin. The results of Zuntz and Hagemann pointed to the same conclusion. The author considers the question to be still an open one. N. H. M.

Influence of Acid Mineral Salts on the Composition of Bones. By H. WEISKE (*Landw. Versuchs-Stat.*, 39, 241—268; compare this vol., p. 848).—The experiments were again made with rabbits; they were all of the same litter, and were 107 days old. The object was to ascertain the effect of a food with an alkaline ash (hay) with or without oats, as compared with a food which gives an acid ash (oats), and partly with addition of dihydrogen sodium phosphate. The exclusive use of oats might have some action, and the addition of the acid salt would intensify the action. The urine of the rabbits fed with hay (0) and with hay and oats (1 and 2) was alkaline, but where oats was given alone (3 and 4) and with the salt (5 and 6), the urine was respectively distinctly and strongly acid. The following table shows the initial and final weights in grams of each rabbit (the experiment lasted three months), and the weight of the dry, fat free skeletons:—

	No. 0.	1.	2.	3.	4.	5.	6.
Initial weight..	1750	2030	1830	1900	1915	2040	1925
Final weight ..	2430	3480	3360	2320	1740	2160	1460
Skeleton	87.66	115.92	115.59	74.13	64.44	67.15	60.37

There was thus a considerable difference in the weight of the bones with the different feeding, Nos. 1 and 2 (fed with hay and oats) being much the heaviest, and 3—6 the lightest. The latter in the fresh condition are, however, relatively the heavier. The bones of 0, 1, and 2 were thicker and harder than the others; those of No. 6 were very thin and breakable. The percentage of ash in the short bones (a), the long bones (b), and the teeth (c) was as follows:—

	0.	1.	2.	3.	4.	5.	6.
<i>a</i>	62.13	60.40	62.70	57.22	60.26	—	58.47
<i>b</i>	66.51	66.29	67.00	60.85	63.46	—	63.38
<i>c</i>	78.72	77.26	78.59	75.68	79.53	—	80.01

With regard to the ash constituents, the differences are not great; but the percentages of lime, phosphoric acid, and carbonic anhydride are generally lower in the ashes of 3 and 6 than of 0, 1, and 2. The magnesia is either the same or higher in 3 and 6 than in the others. But it is rather the amount of ash which varies than the composition. The extraction of mineral matter from the bones is caused by the acid nature of the food. Although of the three normally fed rabbits No. 0 had the lightest skeleton, the percentage amount of total ash and ash constituents was approximately equal in all three; whilst the bones of the other rabbits contained not only absolutely but relatively less ash, and were in part very thin-walled and little capable of resistance.

N. H. M.

Action of Sugars in the Body. By P. ALBERTONI (*Chem. Centr.*, 1891, ii, 44; from *Ann. Chim. Farm.*, 13, 145—159).—Sugar was administered to dogs, which had fasted for 24 hours, and at the end of a given time they were killed by admitting air into the veins. The contents of the stomach were then collected and examined. Experiments were made with maltose, cane sugar, and lactose. Maltose, and especially cane sugar, are absorbed more quickly than glucose. In an hour 70 to 80 per cent. was absorbed. Lactose, however, is different, the amount absorbed being only from 20 to 40 per cent. The absorption is especially small if the solutions are denser than the blood. There is always a certain quantity of sugar found in the tissues outside the stomach. Dilute solutions of lactose are more easily absorbed, the proportion in which it is contained in milk being the most advantageous. Lactose and levulose act on the circulatory system partly like, and partly unlike, glucose, maltose, and cane sugar. The former do not increase the blood pressure, but lessen the pulse frequency; the latter cause a rise of 10—20 mm. in pressure. This is due to their direct action on the blood. Sugar absorbed by the natural channels does not increase the body temperature.

W. D. H.

Formation of Glycogen in the Liver. By E. NEBELTHAU (*Zeit. Biol.*, 28, 138—176).—In the present research, hens and rabbits were the animals chiefly employed, and the principal investigations relate to the influence of certain drugs on the liver glycogen; the animals used had been deprived of food for some days previous to the experiments, and were killed as nearly as possible the same length of time after the administration of the drug. The work of Röhmman is criticised, as he did not pay attention to this latter point; from 20—24 hours after the administration of food or drug being the time when the maximum of glycogen is found. In some cases, the glycogen in the muscles was estimated also, in all cases by Külz's method. The danger of trusting implicitly to single control animals is pointed out, as the glycogen varies greatly in animals

treated in precisely the same way. Full tables of analyses are given throughout.

Chloral hydrate was found to increase the hepatic glycogen, the lethargic condition induced by this drug, and the consequent comparative immobility of the animals, tending to its accumulation; this suggested similar investigations regarding other narcotics; the increase was always found after the administration of chloralamide, paraldehyde, and sulphonal; occasionally the same was observed after the injection of ether, chloroform, and alcohol. Urethane did not produce a marked effect; in only two out of seven experiments was there a slight increase of glycogen in the liver.

Ammoniacal compounds are stated by Rohmann (*Pflüger's Archiv*, 39, 21) to cause increase of the glycogen in the liver; this led him to certain general conclusions regarding the part played by nitrogenous compounds in the formation of carbohydrate material in the body; in the present research, ammonium citrate, ammonium formate, benzamide, formamide, ammonium lactate, and asparagine were used. On the whole, the results obtained confirm those of Rohmann; all increase the liver glycogen; this is true also for lactic acid compounds, which, according to Röhmann, have not this effect.

The febrifuges, antipyrin, kairin, and quinine, all increase the hepatic glycogen. So does section of the cervical spinal cord; this is a confirmation of an old observation of Claude Bernard's.

W. D. H.

Specific Gravity of Blood. By E. L. JONES (*J. Physiol.*, 12, 299—346).—Further observations on the sp. gr. of the blood under various conditions (compare Abstr., 1887, 608) led to the following results.

1. The sp. gr. of the blood varies in different parts of the body, but that from any part bears, *cæt. par.*, a definite relation to that taken from any other part. It is usually the same in corresponding parts of the symmetrical halves of the body. Variations in blood supply to any part are the most frequent causes of alteration of the sp. gr. there, while it remains unchanged elsewhere.

2. The sp. gr. is very high in birds, and low in such animals as frogs.

3. The sp. gr. varies considerably in different persons; it is generally lower in women than in men; before the fifteenth year it is about the same in both sexes; it is higher in old women than old men. In males, the sp. gr. is about 1.066 at birth, and falls gradually for three years to 1.050; then it rises till about the seventeenth year, when it is about 1.058; it remains at about this height till old age comes on, when it falls slightly. In females the chief difference from the foregoing is that during the greater part of life it is 1.0555 instead of 1.058. In girls from 15 to 22 the limit consistent with health is very low, and chlorosis appears to be an exaggeration of this physiological condition.

Further extensive data are given respecting the variations in sp. gr. with complexion, race, physique, food, exercise, sleep, menstruation, anæmia of various kinds, heart diseases, kidney diseases, various fevers, phthisis, syphilis, and many other diseases.

W. D. H.

Glycolysis in the Blood. By M. ARTHUS (*Arch. de Physiol.*, 1891, 425—439).—Lépine and Barral have described in the blood, probably derived from the white corpuscles, a ferment which has the power of destroying sugar, and the absence of which they consider to be a cause of diabetes. In the present experiments, it was found that glycolysis in the blood is a phenomenon of fermentation, but the ferment is absent in the circulating blood. It is formed when the blood is shed, as a result of the disintegration of formed elements other than the red corpuscles. Glycolysis in the blood is thus a cadaveric phenomenon like coagulation. W. D. H.

Influence of Acids and Alkalis on the Alkalinity of Human Blood, and on the Reaction of the Urine. By A. FREUDBERG (*Virchow's Archiv*, 125, 566—600).—The alkalinity of the blood was estimated by a slight modification of v. Jaksch's method of titrating small quantities with very dilute tartaric acid. Recent researches by Bohr have shown that estimation of the carbonic anhydride leads to an incorrect estimate of the alkalinity. The reaction of the urine was estimated by titration with normal soda solution or normal oxalic acid according as the original urine was acid or alkaline respectively. The result of a great number of observations on the blood and urine of patients suffering from a variety of diseases, and also after the administration internally of various acids and alkalis, are given in tabular form, from which the following general conclusions are drawn:—

Hydrochloric acid (4—8 grs. of the officinal acid per diem) does not alter the alkalinity of the blood. Only one exception was noted. The acidity of the urine is, however, always increased.

Lactic acid (10—30 grs.) lessens the alkalinity of the blood by one-fifth to one-fourth. The acidity of the urine is increased, but not markedly so, and not in a degree corresponding with the amount of acid given. It is no doubt to a large extent oxidised in the body.

Tartaric acid (5—10 grs.) lessens the alkalinity of the blood by one-sixth; it also increases the acidity of the urine, but not markedly. It also is burnt to a great extent in the body.

Sodium hydrogen carbonate (5—15 grs.) in three cases increased the alkalinity of the blood by one-fourth; in two other cases there was no change. In all cases the urine was strongly alkaline.

W. D. H.

Xanthine Substances in Urine. By G. SALOMON (*Virchow's Archiv*, 125, 554—556).—Previous investigations having shown that xanthine, paraxanthine, and heteroxanthine are constituents of normal urine, and can be obtained in small quantities from large volumes of urine, the present research is directed to ascertaining whether they can be demonstrated to exist in smaller quantities of urine. The property of the para- and hetero-compounds to form sparingly soluble crystalline compounds with sodium or potassium hydroxide is the most important reaction for separating the members of the group; after the precipitation of these compounds, xanthine remains in solution. The distinction between paraxanthine and heteroxanthine

requires the use of more material, and can be accomplished by the corrosive sublimate and picric acid reactions.

The crystalline compounds of paraxanthine and heteroxanthine with sodium hydroxide are figured, and there is a description of their crystallography. They melt about 300°. The compounds with potassium hydroxide have similar reactions, and a higher melting point.

The paper concludes with a brief account of 21 observations of human urine. In normal urine, paraxanthine appears to be the member of the group most frequently present; in seven cases of various diseases, although the soda reaction was always successful, paraxanthine was sometimes absent.

W. D. H.

Oxidation of Aromatic Substances in the Animal Organism.

By K. KLINGENBERG (*Chem. Centr.*, 1891, ii, 39—40; from *Diss. Rostock Inst. Pharm. physiol. Chem.*).—Aromatic substances belonging to various groups were given to dogs, and their urine for the 24 hours following was examined, with the following results:—

1. Diphenyl is changed in the organism to, and excreted as, parahydroxydiphenyl.

2. Benzidine behaves similarly to quinone, is non-toxic, and is excreted unchanged.

3. Paradibromodiphenyl is also not poisonous, and undergoes no oxidation in the body.

4. Paramidodiphenyl kills in two hours, changing the pigment of the blood corpuscles to methæmoglobin.

5. Carbazole is not poisonous, and is oxidised in the body to hydroxycarbazole, leaving it by the urine as an ethereal hydrogen sulphate.

6. Fluorene is not poisonous. No increase in the ethereal hydrogen sulphates is found after its administration.

7. Phenanthrene and phenanthraquinone are both very well borne. They probably act as antiseptics, and diminish the output of combined sulphuric acid. Glycuronic acid compounds were not found in the urine.

8. Diphenylamine is oxidised in the body to parahydroxydiphenylamine.

9. Diphenylmethane is changed in the body to parahydroxydiphenylmethane.

It thus appears to be the rule that the hydroxylation of aromatic substances within the body, as well as outside of it, consists in the formation of substitution products in which hydroxyl occupies the para-position. If the para-position is already occupied, no hydroxylising action follows.

W. D. H.

Formation of Glycuronic Acid during Inanition. By E. NEBELTHAU (*Zeit. Biol.*, 28, 130—137).—Thierfelder (Abstr., 1886, 572) states that during inanition, and after the administration of chloral hydrate, glycuronic acid in combination as urochloralic acid is found in the urine. The animals with which he experimented had received no food for six days previous to the experiments. Considering that this length of time is sufficient for the complete disappearance

of all the glycogen of the body, he concludes that in the appearance of glycuronic acid in the urine he has proof of the formation of carbohydrate from proteid. Without at all denying this possibility, the present paper points out that Thierfelder's experiments do not prove it, as, after six days' hunger, there is always a considerable amount of glycogen left, both in the liver and in the muscles. The glycogen was estimated by Kulz's method.

W. D. H.

Elimination of Urea in Fever. By H. C. WOOD and J. MARSHALL. (*Journ. of Nervous and Mental Disease*, 1891, 1—9).—It is well known that the amount of urea eliminated during fever is greater than the normal. It seems, however, not to be settled whether this is an integral part of the febrile process, or caused by the action of the excessive heat on certain organs, or by some of the derangements of the bodily functions produced by fever. The latter theory seems probable, as Schleich (*Arch. Exper. Path. u. Pharm.*, 4) and Naunyn (*Berlin klin. Woch.*, 1869), in dogs, and Bartels (*Greifswalder med. Beit.*, 3, 1864), in man, found that artificial elevation of the body temperature produced an increased output of urea.

Many clinical observers have noted that the increased elimination of urea is not necessarily proportionate to the body temperature, and that in the crisis of the fever there is apt to be an extraordinary amount excreted, although the body temperature may be normal or even subnormal; and that in many diseases with low temperature, like cancer, scurvy, diabetes, gout, and especially various affections of the liver, there is again a great increase in urea elimination. In this relation, cases of hepatic fever (that is, the fever produced by stones in the gall-bladder or ducts) become important. The general results of previous and the present experiments show that, even in hepatic fever, a distinct rise of temperature is usually accompanied with an increase in the elimination of urea.

It is, however, most important to remember that temperature is not necessarily a measure of fever; there may be increased heat production, even when the body temperature is below the normal. It is evident that careful calorimetrical studies are urgently needed, by which a comparison may be made between heat production (instead of body temperature) and urea elimination. It may be, for instance, that heat production is much increased during the crisis of a fever. This would explain the critical increase of urea.

The opposite question then arises, whether intense fever with great increase of heat production can exist without corresponding increase in the excretion of urea. Two experiments were made on dogs, which answer this question in the affirmative; after fasting for 24 hours, the urea eliminated was measured for 12 hours, and then the medulla divided at its junction with the pons. This leads to an excessive production of animal heat. The animals lived a few hours after the operation, and the urea excreted during that time was estimated; the results were as follows:—

	Before operation.		After operation.	
	Time.	Urea.	Time.	Urea.
Dog 1	12 hours	10.5 gr.	9 hours	0.9 gr.
Dog 2	12 "	8.3 "	6 "	2.1 "

No urea was found in the blood of either animal. Division of the spinal cord produces no constant result. W. D. H.

Therapeutic and Physiological Effects of Ozone. By D. LABBÉ and OUDIN (*Compt. rend.*, 113, 141—144).—Ozone, prepared by the chemical method, is always impure and poisonous, owing to the presence of phosphorous acid. The authors employ an ozone generator, consisting of a closed glass tube containing rarefied air (which acts as one of the poles), surrounded by a tube on the inner surface of which is a metallic thread. The space between the tubes is 3—4 mm., and across this space pass the sparks that produce the ozone. The tubes being fixed vertically, the slight rise of temperature resulting from the discharge causes a continuous upward current of ozonised air, which mixes with the unaltered air in the apartment. Under these conditions, if care be taken that the quantity of ozone does not exceed 0.011—0.012 milligram per litre, the ozonised air can be breathed even by young children without injurious effect. When the atmosphere is breathed by anæmic subjects, there is a rapid increase in the quantity of hæmoglobin in the blood. Cultivations of the bacillus of tubercle on peptonised gelatin seem to be completely sterilised by the action of the ozonised air.

Ten tubes of the kind described, each being about 800 mm. long, were placed in a laboratory of 300 cubic metres air space, and were actuated by an alternating current from a Gramme machine with a potential of 7000 volts. After about a quarter of an hour, the laboratory was filled with a bluish cloud of aluminium or aluminium oxide, and direct experiment showed that the electric discharge caused the volatilisation of weighable quantities of aluminium from the electrodes. C. H. B.

Quinine as a Protoplasmic Poison. By C. BINZ (*Virchow's Archiv*, 125, 196—197).—In Hermann's *Handbuch*, Engelmann speaks sceptically concerning Binz's observation on the deadly influence of quinine on amoeboid movement. The latter observer now publishes a letter from Engelmann, with an enclosure of a dissertation by ten Bosch, one of his pupils, in which it is shown that Binz is correct, and, moreover, that quinamine has only one-sixth of the toxic power of quinine on protoplasm. W. D. H.

Saponins. By R. KOBERT (*Chem. Centr.*, 1891, ii, 176; from *Pharm. Centralhalle*, 30, 335).—The author considers that there are a series of saponins of the general formula $C_nH_{2n-9}O_{10}$, several of which

are known. Saponins of the same formula and of the same chemical properties appear to have different physiological characteristics, and show great differences in their poisonous action. The sapotoxin of *Agrostemma githago* (corn cockle), one of these substances, is absorbed both by the subcutaneous tissues and by the intestinal canal, and thus acts as a dangerous poison. It is recommended that, before using this seed as a food, the shell and embryo shall be separated.

J. W. L.

Chemistry of Vegetable Physiology and Agriculture.

Manufacture of Pure Yeast. By H. ÉLION (*Bull. Soc. Chim.* [3], 5, 451).—The author describes and figures a steriliser and a fermenting apparatus which is capable of yielding 10 kilos. of absolutely pure yeast at each charge. (Compare Fernbach, this vol., p. 352.)

T. G. N.

Action of Hydrogen Fluoride and of Fluorides on Yeast. By J. EFFRONT (*Bull. Soc. Chim.* [3], 5, 476—480; compare this vol., pp. 477 and 488). Hydrogen fluoride, when present in fermenting saccharine solutions, retards the activity of yeast, and 5.5 milligrams of hydrogen fluoride per 100 c.c. will arrest the fermentation. Small amounts of potassium fluoride (up to 5.5 milligrams per 100 c.c. of solution) augment the activity of the yeast, and although an excess of this salt has a deterrent effect on the fermentation of cane sugar dissolved in distilled water, the quantity may be increased, with beneficial results, to 50 milligrams per 100 c.c. of a wort containing nutrient materials.

T. G. N.

Bread Fermentation. By L. BOUTROUX (*Compt. rend.*, 113, 203—206).—In leavens to which no yeast had ever been added since time immemorial, the author always found yeasts, and he isolated five distinct species, two of which are very active in producing alcoholic fermentation. From the flour, he isolated three distinct species of bacteria: α , which secretes a diastase that dissolves cooked gluten and saccharifies starch paste, but does not attack sugar; β , which produces fermentation, with evolution of gas, in a mixture of flour and water sterilised by heat; and γ , obtained from the bran, which produces a fermentation, with evolution of gas, in a mixture of bran and water. *Bacillus* α followed by yeast produces alcoholic fermentation.

Direct experiment showed that the yeasts active in producing alcoholic fermentation can readily be cultivated in paste, but this is not the case with the yeasts little active in alcoholic fermentation, nor with the bacteria α , β , γ . The yeasts can be cultivated in paste containing 0.3 per cent. of tartaric acid, but this quantity of acid completely prevents the "rising" of paste to which no leaven has been added; a result which shows that the yeast is the essential agent

in bread fermentation, and if the bacteria play any useful part, it is only in the production of the sugar.

Flour charged with its natural microbes, mixed with salt water and pure yeast, and allowed to "rise," contains practically the same proportion of gluten as the original flour, and hence the fermentation of the glucose is not essential, but is a perturbation. Starch also is not affected to any great extent during the process. An aqueous extract of bran, freed from bacteria, saccharifies starch paste, but not crude starch, and this is true also of the amylose secreted by bacillus *a*. The only fermentable material that remains is the soluble part of the flour containing the preformed sugar, dextrin, and salts. The author concludes that bread fermentation consists essentially of the alcoholic fermentation of the sugar pre-existing in the flour. The yeast not only produces the gas that aerates the bread, but it also prevents the development of the bacteria. The difficulty of detecting the yeast in the paste arises from the intimate manner in which it is mixed up with the dough, but the presence of the yeast cells is more readily recognised than the presence of bacteria. C. H. B.

Nitrogen Assimilation of the Leguminosæ. By F. NOBBE, E. SCHMID, L. HILTNER, and E. HOTTER (*Landw. Versuchs-Stat.*, 39, 327—359).—The objects of the experiments were (1) to include some kinds of papilionaceous woody plants, (2) to infect with pure cultivations of bacteria from (a) soil and (b) root nodules, as well as with soil extracts, (3) to ascertain whether one and the same bacterium produces nodules in all leguminous plants, or whether the various orders have their special organisms. The first series of experiments included *Pisum sativum*, *Robinia pseudacacia*, *Cytisus laburnum*, and *Gleditschia triacanthos*. The plants were grown in pure, sterilised sand containing 5 per cent. of powdered peat and 0.5 per cent. of pure chalk, and watered with a nutritive solution containing potassium chloride (0.0161), magnesium sulphate (0.0121), dihydrogen potassium phosphate (0.0133), and ferric phosphate (0.0038 per cent.). The peat was found to be injurious, owing to the formation of acids, and especially so in the first pot of each set, in which no chalk was used. The vessels were of glass and held 6.5 litres. The seeds were sterilised, and were allowed to germinate in sterilised water. The sand in the pots was covered with cotton wool, and the whole heated at 95°. There were 12 pots (5 plants in each pot) which were seeded as follows:—(2) Lupin soil extract, (3) pea soil extract, (4) *Gleditschia* soil extract, (5) *Robinia* soil extract, (6) *Cytisus* soil extract; all these were seeded 7th June; (7) pure cultivation of pea nodule bacteria, (8) pure cultivation of *Robinia* nodule bacteria (both seeded 27th June). Nos. 9—12 were not seeded, but (10) had calcium nitrate (0.973 gram on 8th July), and (12) had ammonium sulphate (0.803 gram on 30th June).

Pisum sativum.—The plants were set on the 21st May, and by the middle of June began to show nitrogen hunger. On the 27th of June, the pea soil extract (3) began to have an effect; and on the 30th, the plants seeded with *Gleditschia* (4) and *Cytisus* (6) soil extracts began to improve, whilst the *Robinia* soil extract (5) did not

show effect until the 10th of July. The lupin soil extract had no effect at all (owing, perhaps, to its not being fresh enough), and the subsequent application of fresh soil extract also had no effect, being probably too late; the negative results obtained with Nos. 7 and 8 are also supposed to be due to the lateness of the application. Calcium nitrate and ammonium sulphate, produced a beneficial effect two and three days after their application. The plants of both these pots produced flowers, whilst not one of the successfully infected plants did. On the other hand, almost all of the plants which did not recover from their state of nitrogen hunger (Nos. 2, 7, 8, 9, and 11), in spite of their scanty growth, produced flowers, and some even small fruit. The results confirm those obtained by Hellriegel, that the nodule bacteria give an impetus to vegetation, and hinder flower and fruit formation. All the successfully infected plants had nodules; one plant (in pot 4) had 4572 normal nodules. The nodules were almost all in the upper parts of the roots; this was also found to be the case in the experiments with other plants. The quantitative results as regards total produce and nitrogen are given in the table on next page.

Robinia pseudacacia.—The period of hunger began at the end of June and ceased first in the case of the plants seeded with the *Robinia* nodule bacteria (No. 8), and next where *Robinia* soil extract was given (5). The extracts of *Cytisus* and *Gleditschia* soil were slower in producing an effect; whilst the lupin and pea soil extracts, and the pea nodule bacteria, had no effect at all. Calcium nitrate, and ammonium sulphate, caused a distinct improvement two days after their application, and the plants so treated ripened soonest, and began to lose leaves when the infected plants were still quite fresh. The roots of the plants supplied with ammonia had no nodules, but those which had nitrate, and some of the unsuccessfully seeded pots had. It is at least possible for *Robinia* to exist without nodules (compare Frank, *Ber. deut. bot. Ges.*, 1890, 292). The nodules are generally larger, but less numerous, than on pea roots. All the successfully seeded plants had nodules. In the case of the plants infected with pea nodule bacteria, and of the other plants which were not intentionally infected, but which produced nodules, there was no increased growth. Frank's view that the bacteria have no object when the soil contains nitrogen seems to be correct. If it is assumed that the nitrogen assimilation takes place through the leaves, it is probable that the nodules in pots 2, 3, 7, and 9 were formed at a time when the roots still contained enough nourishment for them, but that the leaves were too much exhausted for the bacteria to enable them to recover. The results of the experiments indicate an essential difference in the behaviour of various soil extracts; *Robinia* soil extracts acted (with *Robinia*) the most quickly, and pea soil not at all, whilst other extracts were intermediate in their action. This point is further illustrated by special experiments described further on. Suitable infection had a greater vegetative action than an excess of ammonia or nitrate. The quantitative results—amount of dry produce, and the amount of nitrogen in produce, and in seed sown—are given, together with those obtained with peas, in the following table:—

	Seeding.	Dry produce (1 plant).			Nitrogen.		
		Stems and leaves.	Roots.	Whole plant.	In seed sown (1 seed).	In produce (1 plant).	Gain or loss.

Cystisus laburnum.—There was no marked difference in the plants of the different pots by the 12th August, when the plants were taken up. On examining the roots, however, it was found that many of them had nodules, and it was noticed that the corresponding plants had new leaves still quite fresh. It seems probable that if the plants had been left longer, these plants would have continued to grow. No analytical results are given.

Gleditschia triakunthos.—No difference in the various plants was to be seen by the middle of July, and there were no symptoms of nitrogen hunger, but the plants grew very slowly. The plants supplied with nitrogen began to darken about eight days after the application. At the time of taking up (6th October), five plants in pot 10 and two in pot 12 were still healthy; all the others had lost all their leaves. The roots of all the plants were free from nodules. The dry matter of the produce (one plant) varied from 0.603 to 1.036 gram, and the nitrogen from 0.0085 to 0.0111 gram (one seed sown contained 0.0107 gram) in the pots where no nitrogen was given, so that there was, practically, no gain in any case. The ammonia and nitrate pots gave respectively (in one plant) 1.016 and 1.145 grams of dry matter and 0.0314 and 0.0306 gram of nitrogen.

As already shown by Hellriegel, extracts of various soils have quite different action on various plants; this depends not on the number (as Frank assumes), but on the kind, of organisms present.

The second series of experiments was similar to the first, except that only half the amount of peat was mixed with the sand. The plants were *Pisum sativum*, *Lupinus luteus*, and *Phaseolus vulgaris*, but the lupins did not grow well, owing, it is supposed, to unfavourable conditions of the sand.

Pisum sativum.—The plants were set on the 7th August, and were infected on the 14th with pure cultivations of bacteria from various sources as follows:—(1) Pea nodules, (2) pea soil, (3) lupin nodules, (4) lupin soil, (5) *Robinia* nodules, (6) *Robinia* soil. All the plants reached the period of hunger 14 days after the infection. Seven days later the plants of pots 1 and 2 began to acquire a darker colour, and five days later still the plants of pot 3 showed an increase of chlorophyll. The *Robinia* bacteria remained without action. When taken up (21st October), most of the plants had flowered; in the case of pots 1—3, the flowers fell off without forming fruit; whilst the small plants of pots 4—6 formed each one fruit with one seed. This result corresponds with that obtained in the first series with peas. The roots of the plants of pots 1—3 had all nodules; those of pots 4—6 had none. The nodules of pots 1 and 2 were very numerous, sometimes small and round, sometimes 2 mm. long and 0.8 mm. wide, and the bacteroid tissues rose-coloured; the nodules of pot 3 grew into each other, sometimes extending 0.5 to 1 cm., and giving the root the appearance of being thickened. The nodules produced by pea nodule bacteria were formed on roots of the 2nd order; those produced by lupin nodule bacteria on roots of the 3rd order. The result of greatest interest is that the same (pea nodule) bacteria which, in another experiment, had no effect on *Robinia* produced nodules

2nd Series.

on the pea roots (the nodule formation being accompanied by much increased growth and nitrogen assimilation), whilst bacteria (from *Robinia* nodules), which had produced nodules on *Robinia* roots, had no effect on the peas. The numerical results are given with those obtained with beans in the table on the preceding page.

Phaseolus vulgaris.—The plants were set the 21st August, and infected on the 26th and 27th August, as follows:—No. 1, not infected, calcium nitrate, (2) bean soil extract, (3) pea soil bacteria, (4) lupin soil bacteria, (5) *Robinia* soil bacteria, (6) pea nodule bacteria, (7) lupin nodule bacteria, (8) *Robinia* nodule bacteria, (9 and 10) nothing. When taken up (27th November), the plants of pots 1, 4, 5, 7—10 were free from nodules; those infected with bean soil extract (2) and with pea soil and pea nodule bacteria (3 and 6) had numerous nodules; those of pot 3 being the largest. The view that beans produce nodules, even under sterilised conditions, is therefore erroneous. The nodules of the plants in pots 2 and 4 were in roots of the 3rd order, and from most of them there proceeds a root of the 4th order which often bears nodules, and is thicker than the root on which the nodule is situated. The roots have grown out of the nodule, and are remarkable on account of the large amount of crystals of calcium oxalate they contain at the point where they arise, proving that, in the roots as well as in the nodules, lively chemical changes take place, the products of which are not carried up into the above-ground portions, but to the roots. Moreover, these observations indicate that the changes connected with the enriching of the plant with nitrogen take place in the nodules. This does not touch the question whether the bacteria assimilate directly the free nitrogen of the air or water, or whether, as seems more probable, the crude nitrogenous material is brought to them from the leaves. The table on the preceding page shows the results of the second series of experiments with peas and beans.

Photographs are given of some of the plants at different periods of growth, and, also, of some of the roots.

In order to show the effect of various nodule organisms in different plants under absolutely identical conditions, five pots were prepared, into each of which 1 lupin, 1 pea, 1 *Robinia*, 1 *Cytisus*, and 1 *Gleditschia* were planted. The pots were seeded with bacteria from (1) *Gleditschia* soil, (2) pea nodules, (3) *Robinia* nodules, (4) lupin nodules. No. 5 was not seeded. All the plants showed nitrogen hunger about a month after they were planted; afterwards each plant which had been infected with its own organism (except the *Cytisus* and *Gleditschia*) began to grow better than the others. Only the *Robinia* of series 1, the pea of series 2, the *Robinia* of series 3, and the lupins and *Robinia* of series 4 had nodules. The *Robinia* nodules of series 1 and 4 were small and few.

In the two series of experiments, the evaporation from the plants was ascertained by weighing every day, and so much water given as was necessary to keep the weight at 60 per cent. of the weight of saturation. The results obtained with peas and *Robinia* are shown in curves, and are of great interest, inasmuch as the evaporation is an approximate measure of assimilation and growth.

N. H. M.

Artificial Infection of *Vicia faba* with *Bacillus radiculicola*. By M. W. BEYERINCK (*Forsch. a. d. Gebiete d. Agr. phys.*, 14, 57—58; from *Dot. Zeit.*, 1890, 837).—Beans were grown in specially constructed pots, and the same precautions taken for keeping out air organisms as Prazmowski used in his experiments. Some of the plants were infected with *Bacillus radiculicola* (from bean nodules), and others left unseeded. All the infected plants had nodules, whilst none of the uninfected plants had any: the presence or absence of potassium nitrate or ammonium sulphate had no influence on the infection.

When the bacteria are grown in agar-agar containing only salts and cane-sugar, the growth ceases as soon as the small amount of assimilable nitrogen present is used up. The assimilation of free nitrogen does not, therefore, take place under these conditions, and at a temperature between 10° and 20°. But the bacillus has the power of utilising the smallest traces of combined nitrogen (nitrate, ammonia, peptone, or amide) in presence of a carbohydrate, especially cane sugar. This power of taking up the minutest traces of nitrogen compounds throws a new light on the symbiosis. In the nodules, the last traces of combined nitrogen are accumulated as reserve albumin in presence of the carbohydrates of the plant, giving rise to a complete nitrogen exhaustion of the soil round them. The author is acquainted with another organism (*Streptotrix humifixa*), which also, in presence of carbohydrates, causes a complete nitrogen exhaustion of the soil, but does not live in symbiosis with Papilionaceæ.

The various papilionaceous bacteria differ more than the author formerly assumed. *Vicia faba* infected with *Bacillus ornithopi* produced no nodules. The difference in the bacteria of beans and serradella (*Ornithopus sativus*) accounts for the fact that serradella was found free from nodules growing in a garden between beans which had numerous nodules.

N. H. M.

Formation of Starch from Formaldehyde. By T. BOKORNY (*Chem. Centr.*, 1891, ii, 120—121; from *Ber. deut. bot. Ges.*, 9, 103—106).—In continuation of previous researches on the formation of starch from methylene dimethyl ether by algæ (*Landw. Versuchs-Stat.*, 36, 229—242), the author has grown algæ (*Spirogyra majuscula*) in solutions containing sodium hydroxymethylsulphonate, and has observed the formation of very considerable quantities of starch. The experiments lasted five days, the vessels being kept in an atmosphere free from carbonic anhydride, and exposed to the light during the daytime. Blank experiments were carried out at the same time, with the result that, in these cases, no formation of starch occurred. In order to neutralise the sodium hydrogen sulphite which is formed from the sulphonate, a little dipotassium or disodium phosphate was added to the solutions.

The solutions contained 1 part of the sulphonate in 1000.

J. W. L.

Ripening of Cherries: Fermentation of Cherry and Currant Juice, and Colouring Matters of Red and Black Currants. By W. KHEIM (*Zeit. anal. Chem.*, 30, 401—407).—The first part of the

following research deals with the changes in chemical composition which take place during the growth and ripening of the fruit of *Prunus cerasus*. The variety experimented with was the early egriot, specimens of which were gathered from a single tree at intervals of 7—10 days. Table I gives the results of the analyses in percentages.

TABLE I.

Date of gathering.	Average weight in grams.	Water per cent.	Dry substance per cent.	Total acid calculated as malic acid per cent.	Invert sugar. per cent.
15th May, 1890..	0·6375	88·88	11·12	0·213	2·74
21st May, 1890 ..	0·8259	83·73	16·27	0·310	3·13
28th May, 1890..	1·321	82·13	17·87	0·412	4·14
10th June, 1890..	3·08	83·63	16·35	0·421	9·12
19th June, 1890 .	3·719	81·223	18·777	0·462	10·26

Date of gathering.	Saccharose per cent.	Ash. per cent.	Acids present.	Glucoses present.
15th May, 1890....	0·187	0·478	Citric, malic, and succinic	Not ascertained.
21st May, 1890	—	0·516	Ditto	Dextrose, levulose, and inosite.
28th May, 1890....	0·28	0·646	Ditto	Ditto.
10th June, 1890....	1·17	0·656	Malic and citric	Not examined.
19th June, 1890 ...	—	0·739	Ditto	Dextrose, levulose, and traces of inosite.

On the four later dates, the sugar in the leaves was estimated; 0·436, 1·465, 1·321, and 0·813 per cent. respectively being found. This sugar did not reduce Fehling's solution until after inversion. In addition to the vegetable acids above mentioned, crystals of calcium oxalate were seen under the microscope, and traces of formic and acetic acids were obtained by distilling the juice. The distillate from currant juice gave indications of an aldehyde. The progressive increase in the percentage of acid during the whole period is not in harmony with the old view, that the sugar was formed at the expense of the acid. The disappearance of succinic acid, as ripening is approached, suggests the theory that the other acids are formed synthetically from oxalic and succinic acids. The presence of saccharose alone in the leaves (which organs are doubtless the seat of the genesis of the carbohydrates), in proportions which increase as the ripening stage is approached, but subsequently diminish, tends to indicate that the formation of saccharose is the first stage in the production of the sugars, and that the transformation into glucoses in

the fruit is effected by the acids there present. No starch was detected at any stage in the fruit itself; the parenchyma cells of the peduncle showed starch granules increasing in amount as the fruit ripened. The ash of the second, third, and fifth samples was analysed with the following results. The portion insoluble in hydrochloric acid was rejected from the analysis.

Ash of Cherries.

		21st May.	28th May.	19th June.
Portion soluble in water.	SiO ₂	—	1·510	1·8420

Thirteen experiments were conducted on the fermentation of the juice of cherries and red currants, both with and without the addition of yeast, sugar, and water, and the resulting wines were fully analysed. The results are too voluminous for reproduction. The most notable features are the invariable diminution in the amount of acid, which diminution was the more considerable as the fermentation was the more vigorous. In no case did the addition of sugar cause a proportional increase in the glycerol, but merely a comparatively small augmentation. The sugar which escaped fermentation was entirely converted into levulose.

The qualitative results of the action of various reagents on the juice of black and red currants, as well as the characters of their absorption spectra, indicate that the colouring matters of those fruits are closely allied if not identical. Graphic representations of these spectra, as also those of cherries, bilberries, mallows, and phytolacca berries, rosaniline, ponceau, and rocellin are given.

M. J. S.

Chemical Composition of some Leguminous Seeds. By E. SCHULZE, E. STEIGER, and W. MAXWELL (*Lundb. Versuchs-Stat.*, 39, 369—326).—*Lupinus luteus*.—After giving the result of the quantitative examination of lupin seeds, the authors give a detailed account

of the methods employed in the estimation of the various constituents (compare Schulze and Steiger, *Landw. Versuchs-Stat.*, 36). The analyses were made with two samples of seeds, freed from skins (1 and 2) and with the skins themselves (3). The following table shows the distribution of the nitrogen percentage in the dry matter :—

	1.	2.	3.
Nitrogen as proteids (conglutin, legumin, and albumin)	7.86	9.24	0.61
Nitrogen as nuclein (and plastin?)	0.10	0.05	0.11
" non-proteids	1.24	0.24	0.02
Total nitrogen	9.20	9.53	0.74

In the next table, the percentage composition of the same samples is given, whilst the composition of the entire seeds is shown in the fourth column. These last numbers were obtained by calculation from the result of the other analyses. The seeds contained 26 per cent. of hulls.

	1.	2.	3.	4.
Proteids	44.48	52.30	3.81	36.79
Nuclein	0.80	0.40	0.88	0.67
Alkaloids (lupinine, lupinidine)	1.46	(1.46)	—	1.08
Leathin	(2.11)	2.16	—	1.58
Cholesterol	0.17	0.18	—	0.13
Glycerides (and free fatty acids)	6.63	5.83	—	4.61
β -Galactan	6.37	10.20	—	7.63
Paragalactan	10.89	8.76	17.91	11.73
Crude fibre	5.21	5.83	54.34	18.21
Soluble organic acids (citric, malic, and oxalic acids)	2.09	2.21	—	1.59
Ether extract (lupeol, &c.)	—	—	0.79	0.21
Soluble carbohydrates	—	—	5.47	—
Ash	4.35	4.27	1.73	3.64
Not determined and loss	15.73	6.40	15.07	12.13

The digestibility of the seeds freed from their skins was determined by Stutzer's method in the powdered seed (freed from fat). The two samples (1 and 2) gave residues containing only 1.09 and 0.53 per cent. of the original total nitrogen. The dry residue (mean) after digestion, was 6.87 per cent. of the dry matter of the shelled seed. It seems probable that the pancreatic extract has no action (or a very slight action) on the paragalactan (compare *Ber.*, 24, 183).

Vicia sativa, *Pisum sativum*, and *Faba vulgaris*.—The seeds were analysed entire. The following table shows the percentage composition of the dry matter :—

	<i>Vicia sativa.</i>	<i>Pisum sativum.</i>	<i>Faba vulgaris</i>
Nitrogen as proteids.....	4.241	3.583	3.801
„ nuclein	0.291	0.143	0.239
„ non-proteids.....	0.504	0.425	0.435
Total nitrogen	5.039	4.151	4.574
Proteids	25.46	21.50	22.81
Nuclein	2.33	1.14	1.91
Lecithin	1.22	1.21	0.81
Cholesterol	0.06	0.06	0.04
Glycerides and free fatty acids.....	0.91	1.87	1.26
Soluble organic acids (as citric acid)	0.50	0.73	0.88
Cane sugar and galactan	4.85	6.22	4.23
Starch	36.80	40.49	42.66
Crude fibre	4.89	6.08	7.15
Paragalactan and substances not determined ..	21.60	17.29	15.83
Ash	2.90	3.46	2.92

With regard to digestibility, of 100 parts of nitrogen the residues of the three seeds, after treatment with pancreatic extract, contained respectively 5.77, 3.64, and 5.34 parts. Besides the substances determined, the seeds of *Vicia sativa* contained vicine, convicine, betaine, cholin, and amygdalin; the seeds of *Pisum sativum* contained cholin and a base similar to betaine.

Soja hispida.—The seeds contained only a small amount of starch, but more cane sugar than the other seeds. They also contain a considerable amount (1.64 per cent.) of lecithin. N. H. M.

Influence of Iron and Calcium Sulphates on Nitrification. By P. RICHARD (*Compt. rend.*, 112, 1455—1458).—In a pure siliceous sand, kept sufficiently moist and containing unaltered nitrogenous organic matter (cotton oilcake) to the extent of about 1 gram of nitrogen per kilo., the addition of 0.1 per cent. of iron sulphate reduced the loss of nitrogen for seven months from 47.65 to 18.36 per cent., and increased the gain of nitric nitrogen from 1.43 to 10.40 per cent., and that of ammoniacal nitrogen from 4.49 to 11.22 per cent.

With 10 per cent. of clay mixed with the sand, the loss of nitrogen was not sensibly reduced, the gain in nitric nitrogen was increased from 5.10 to 15.92 per cent., and the gain in ammoniacal nitrogen reduced from 16.94 to 12.75 per cent. by the use of the iron sulphate.

Sand containing 1 per cent. of calcium carbonate with iron sulphate did not show any sensible reduction of the loss of nitrogen; the gain of nitric nitrogen diminished from 5.10 to 2.55 per cent., and of ammoniacal nitrogen increased from 6.43 to 10.40 per cent.

In sand containing clay and calcium carbonate, iron sulphate reduced the loss of nitrogen from 31.63 to 23.87 per cent., diminished the gain of nitric nitrogen from 7.14 to 6.43 per cent., and augmented the gain of ammoniacal nitrogen from 18.57 to 26.73

per cent. In the same medium, double and triple allowances of iron sulphate have lessened the loss of nitrogen, gradually diminished the gain of ammoniacal nitrogen, and increased the gain of nitric nitrogen.

Iron sulphate hinders the decomposition of nitrogenous matters, and favours nitrification.

Using iron lactate with a soil containing sand, clay, and calcium carbonate, the iron being in the same proportion as before, loss of nitrogen became 0.20 per cent., gain in nitric nitrogen increased to 22.34 per cent., and gain in ammoniacal nitrogen decreased to 3.57 per cent.

Iron salts appear in general to be detrimental to the ferments destroying nitrogenous matters, but the organic salts of iron favour nitrification.

Ferric oxide added to a complete soil (sandy, clay, and chalk) to the extent of 0.2 per cent. reduced the loss of nitrogen from 31.63 to 21.43 per cent., increased the gain of nitric nitrogen to 19.69 per cent., and reduced the gain of ammoniacal nitrogen to 10.71 per cent. Ferric oxide does not hinder the decomposition of nitrogenous matters; it appears to moderate the energetic action of calcium carbonate, and clearly to favour nitrification, by fixation of ammonia in the same way as clay, and by its oxidising properties.

Calcium sulphate, when introduced to the extent of 0.5 per cent. in the same soils, is found to be superior to iron sulphate in regard to nitrification. In pure siliceous sand, the gain of nitric nitrogen is raised to 11.43 per cent., in sand with chalk to 13.67, in sand with clay to 23.67, and in a complete soil to 34.48 per cent. As a nitrogen preserver, its action is more efficacious than that of iron sulphate, except in the case of siliceous sand, an exception accounted for by its inferior solubility. Calcium sulphate does not retard the decomposition of nitrogenous matters by ferments.

Iron sulphate would be usefully employed to fix ammonia in positions where it is rapidly formed, as in liquid manure ditches, manures, and sewage. Its use would be prejudicial in connection with organic manures which decompose but slowly, on account of its antiseptic properties.

Iron sulphate would be advantageously used as a manure in wet, sandy soils poor in clay, chalk, and ferric oxide. All other soils would be more benefited by the employment of calcium sulphate.

Iron sulphate would be useless, if not detrimental, in the case of ferruginous soils.

Chlorosis due to starving, and not to the influence of meteorological conditions or the ravages of parasites, might be overcome by the use of calcium sulphate as well as iron sulphate.

The practice of adding natural marls containing gypsum is amply justified, as ammonia is fixed by the clay and calcium sulphate, the destruction of nitrogenous organic matter is lessened by the calcium carbonate and the losses of nitrogen diminished, nitrification is rendered regular, and the fixation of atmospheric nitrogen is much promoted.

W. T.

Formation and Oxidation of Nitrites in Soils. By S. WINOGRADSKY (*Compt. rend.*, 113, 89—92; compare Warington, *Trans.*, 1891, 484).—Liquids containing ammonium sulphate and other mineral salts, together with magnesium carbonate, were sown with soils from various parts of the world. In all cases, nitrification started with the formation of nitrites, nitrates not appearing in quantity until the ammonia had disappeared. When, however, successive cultures were made from the soils, the later generations did not preserve the parallelism. With European soils, the formation of nitrates diminished after six or eight generations, and at last ceased; with soil from Quito, nitrites were still being formed after twelve generations; whilst with other South American and African soils, the rate of formation of nitrates was not only maintained, but could be augmented by replenishing the solution with ammonium salts.

In the attenuated cultures, especially in those in which nitrates had been formed, there were observed several kinds of microbes, which bore a general resemblance to the nitrous organism (*nitro-monade*). Some of these were isolated, and were found to retain under culture their power of oxidising ammonia, but to lose after a few generations that of oxidising nitrites. An endeavour to isolate the nitric organism from Tunis soil by gelatin culture also gave negative results; but the method by which the nitrous microbe had been isolated proved successful.

A solution of nitrites was sown with Quito soil, and, as soon as the oxidation had become regular, a little drop of the culture was sown in gelatinous silica. Colonies of two different organisms developed, one of which proved to be the nitric microbe. It is a very small, irregular, bent rod, which bears no resemblance to the nitrous organism separated from the same soil. It rapidly converts solution of nitrites into nitrates, but has no action on ammonia.

Organisms of similar function were found in the Java and Zurich soils, and it is probable that, like the nitrous organisms, they constitute a group, of which each soil contains a particular species.

JN. W.

Nitric and Ammoniacal Nitrogen as Manures. By PAGNOUL (*Ann. Agron.*, 17, 274—283).—Muntz has shown that plants receiving nitrogen only in the form of an ammonium salt can live in a sterilised soil in which nitrification of the ammonia does not take place, and hence concludes that ammonia compounds are directly assimilable by plants; in ordinary soil, well provided with the nitrifying ferments, however, ammonia cannot persist, and plants must nearly always absorb nitrogen as a nitrate.

The author's experiments of 1890 on this point were made in four glass flower pots, holding 2—3 litres, and furnished with tubulures at the bottom, connected by india-rubber tubes to four small flasks. A layer of gravel was placed in each pot, and they were filled with the following media:—

A. Good, arable soil containing, per cent., 0.102 N, 0.098 P_2O_5 , 0.290 K_2O , and 1.547 CaO .

B, C, D. Siliceous sand, mixed with 10 grams calcium sulphate.

C received in addition an admixture of 20 grams of the soil A, in order to supply it with the nitrifying ferments.

Similar seeds were sown in the four pots, and A was watered throughout with nothing but pure distilled water. B received at intervals 25 c.c. of a solution containing 100 milligrams N as ammonium sulphate, and 100 milligrams P_2O_5 as superphosphate. C received the same quantities of ammonium sulphate and superphosphate as B, and, in addition, 100 milligrams of potash as potassium chloride in each 25 of nutritive liquid. D received in each 25 c.c. of solution 100 milligrams N as sodium nitrate, and the same quantities of superphosphate and potash salt as C. 20 estimations were made of nitric and ammoniacal nitrogen in the drainage water of each flask at intervals, the nitric nitrogen by a colorimetric process with diphenylamine, and the ammonia by distillation with magnesia and Nesslerising. Nine cuttings of the crops were taken from May 14 to August 22, simultaneously in all the pots, and the total weights obtained were:—

A.	B.	C.	D.
31.7	59.5	106.3	103.1 grams.

Thus the sterile sand, with suitable manures, gave much better yields than the good soil without manure, the organic nitrogen in the latter not being transformed into assimilable compounds with sufficient rapidity. In the presence of soil containing nitrifying ferments, the ammonium sulphate proved as efficacious as its equivalent of sodium nitrate, but the absence of this ferment reduced the yield to one-half.

The results of analyses of the drainage waters on 20 different dates may be summarised thus:—In the drainage of pot A, the barest traces of nitric and ammoniacal nitrogen were found, generally about 0.2 milligram per litre. In that of pot D, which received altogether 1100 milligrams of N as sodium nitrate, mere traces of ammonia were present; nitric nitrogen was found in large quantity (up to 110 milligrams per litre) immediately after each fresh supply of the manurial liquid, but after eight or 10 days, or five or six percolations through the soil, the quantity sank to traces or *nil*, if the plant was in active growth. In the drainage of pot C, nitric and ammoniacal nitrogen were found in something like equal quantities on the whole set of estimations, so that although it is certain much of the ammonia was nitrified, it is not certain whether all the nitrogen that entered the plant was in the form of nitrate. In the drainage of B, large quantities of ammonia were always found, and these increased towards the end of the experiment through accumulation of unused ammonium sulphate; nitric nitrogen was either absent or present in traces only, except towards the end of the experiment, by which time a little nitrifying ferment may have got into the sand. Although the ammonium salt is shown to be far less favourable (in the absence of nitrifying ferments) to the vegetation than the nitrate, the considerable crop obtained renders it extremely probable that some of it was directly assimilated.

Estimations of nitric and ammoniacal nitrogen in the plant itself were made on the cuttings of June 11 and 23 and July 7. The plant from A never contained nitrate, and the merest traces, if any, of ammonia; in that from B, no nitrate was present, but there was a small proportion of ammoniacal nitrogen (13—14 milligrams per 100 grams) on each date; the plants of C and D contained the merest traces, if any, of ammonia, but nitric nitrogen was present in very variable quantity, according to the time which had elapsed since the last supply of nitrogenous manure to the plant; 18 days after, the quantity was 3 and 8 milligrams per 100 grams; seven days after, 140 milligrams per 100 grams. When supplied in abundance, nitrate is first stored in the plant and then its nitrogen is assimilated.

The author's experiments confirm the views of Muntz, already mentioned. J. M. H. M.

Loss of Nitrogen during Decomposition of Nitrogenous Organic Matter, and the Means of Limiting or Avoiding it. By J. H. VOGEL (*Bied. Centr.*, 20, 562—564; from *J. f. Landw.*, 38, 327—334).—According to v. Krause (*J. f. Landw.*, 38, 1), superphosphate is an excellent preservative for manure, and is preferable to superphosphate-gypsum, owing to the greater amount of soluble phosphates it contains. With readily soluble phosphates, there seems to be a gradual formation of calcium carbonate and ammonium phosphate; the free acid takes up the ammonia more quickly, but there remains only a small amount of soluble phosphates which fix ammonia.

The author refutes these views of v. Krause. Small losses of soluble salts cannot be avoided with farm-yard manure. The loss of phosphoric acid is, however, slight, but may be considerable if superphosphate is added to it, so much so that any beneficial action of the superphosphate is more than cancelled. Moreover, the soluble phosphoric acid of the superphosphate, or superphosphate-gypsum, does not combine with the ammonia which is liberated from the farm-yard manure, but mostly goes over into the insoluble state: ammonium sulphate and sparingly soluble calcium phosphates are formed, with merely a trace of ammonium phosphate. The very favourable effect of phosphoric acid in preserving manure is due, in the first place, to its power of so changing the fermentation that no free nitrogen, or but little, is formed. The liberation of nitrogen was shown by Dietzell to be prevented not only by phosphoric acid soluble in water, but also by phosphoric acid soluble in citrate, and the author has already proposed using a preparation which contains, besides calcium and magnesium sulphates, also a large amount of phosphoric acid soluble in citrate.

The loss of free nitrogen, when gypsum is used alone, is not nearly so great as the advantage which follows from the fixation of ammonia.

N. H. M.

Manuring Experiments with Rice. By O. KELLNER, Y. KOZAI, Y. MORI, and M. NAGAOKA (*Landw. Versuchs-Stat.*, 39, 361—382).—In order to ascertain the food requirements of rice, a number of experiments were made in which rice was grown in soil variously

manured. Wagner's method of small plots was employed: these were made by sinking wooden frames, with a surface of nearly a square metre, about 50 cm. into the ground. The air-dried soil (which was of volcanic origin) contained:—Nitrogen, 0.608; phosphoric acid, 0.448; potash, 0.232; and lime, 0.248 per cent. There were five series: the first contained six unmanured plots, three with nitrogen and potash, three with phosphoric acid and potash, and three with phosphoric acid and nitrogen. In the second series, all the plots had the same amounts of phosphoric acid and potash, and varying amounts of nitrogen. In the third series, all the plots had the same amount of nitrogen and potash, and varied amounts of phosphoric acid. In the fourth series, the amounts of nitrogen and phosphoric acid were the same in each case, and the potash varied. In the fifth series, all the plots had nitrogen, phosphoric acid, and potash, and different amounts of lime.

The unmanured plots gave a very poor yield, and the application of much nitrogen and potash alone had no beneficial effect. Phosphoric acid was found to be a most important manure, whilst potash did little or no good. The results showed that, for its full development, rice required a manuring of 7.5 kilos. of nitrogen and 12.5 kilos. of phosphoric acid per one-tenth hectare; in some cases, a small amount of potash is necessary. The usual manuring of the district includes far too little phosphoric acid.

With regard to the effect of the manures on the composition of the crops, it was found that the produce of the unmanured plots, and of those which had nitrogen and potash, was the richest in nitrogen. The produce poorest in nitrogen was obtained from those plots which were manured with much phosphoric acid and potash, but with little or no nitrogen. When much nitrogen was applied, the total dry produce contained more than 1 per cent. of nitrogen, the excess being chiefly in the straw.

The differences in the amounts of phosphoric acid in the produce of the different plots were generally analogous to the difference in the amounts of nitrogen. When no nitrogen, but much phosphoric acid was applied, the straw remained poor in phosphoric acid; this is ascribed to the quick ripening of the plants. N. H. M.

Analytical Chemistry.

The True Litre or Mohr's Litre, for Volumetric Analysis. By W. FRESSENIUS (*Zeit. anal. Chem.*, 30, 461—465).—The expressed desire that the German Imperial Standards Commission should undertake to test and certify measuring vessels for chemical purposes has brought into prominence the question whether the true litre ought to be used for this purpose, or the very prevalent "Mohr's litre," which is about 2 c.c. greater than the true litre. The Commission, although holding itself bound by the terms of its constitution not to

authenticate as a litre measure any vessel which did not conform to the true definition, nevertheless took steps to ascertain the opinions of various scientific men with regard to the question. In view of the common practice of expressing the specific gravities of liquids with reference to water of the same temperature (and that a mean working temperature) as unity, which practice is already recognised by the Commission in testing hydrometers, and considering the convenience of expressing the unit of weight and that of volume by an identical number under practical working conditions, as well as the confusion which would result from neglect of the corrections rendered necessary by the employment of "true" litre vessels at any temperature other than 0° , the author suggests that Mohr's litre should be retained for volumetric work, and that the certificate to be issued should be worded in some such manner as the following:—"The flask X, filled with water of 17.5°C. , so far that the mark is tangent to the lower meniscus, contains an amount of water which equipoises a brass kilogram in air of 760 mm. pressure, and therefore holds a so-called Mohr's litre."

M. J. S.

Neutral Litmus Paper. By K. MAYS (*Verh. d. Naturhist.-Med. Verein Heidelberg, N.F.*, 3, 295—298).—An aqueous extract of commercial litmus is acidified with hydrochloric acid, and placed within a parchment paper dialyser for eight days, there being running water outside. Litmus is a colloid substance, and in this way is freed from saline and other impurities. Paper impregnated with this neutral litmus solution is perfectly satisfactory for the determination of reaction.

W. D. H.

Test for Hydrogen Peroxide. By G. DENIGÈS (*Bull. Soc. Chim.* [3], 293).—When a drop of a 10 per cent. solution of metaphenylenediamine chloride is boiled with a few drops of water and a drop of hydrogen peroxide solution, a carmine-red coloration is produced. This reaction will detect 0.005 milligram of hydrogen peroxide in a drop of water, but is affected by the presence of nitrites. The test is thus modified, to be independent of the presence of the latter compounds:—One or two drops of metaphenylenediamine chloride is added to 1 c.c. of ammonia solution containing a few drops of hydrogen peroxide solution; the mixture is boiled for some minutes, when the previously colourless solution becomes blue, of intensity corresponding with the peroxide present; addition of alkali hydroxide solution changes the colour to red. In reference to a former communication (*Abstr.*, 1890, 1185), the author states that the molybdosulphuric acid used for the detection of hydrogen peroxide is made by mixing equal volumes of a recently prepared ammonium molybdate solution (10 per cent.) and concentrated sulphuric acid; the solution, which becomes bluish on keeping, is rendered colourless by warming, and its sensitiveness is unimpaired.

T. G. N.

Estimation of Sulphur in Iron. By v. REIS and F. WIGGERT (*Chem. Centr.*, 1891, ii, 218—219; from *Stahl u. Eisen*, 11, 480—483).—The apparatus employed by the authors is represented in the

accompanying figure. *A* is a distillation flask, on the side-tube of which a small bulb *B* is blown, from which a side-tube leads to the absorption apparatus *C*. The stoppered funnel *D* has a ground stopper on the lower limb, which fits the neck of *A*. *E* is a small

washing flask for the carbonic anhydride, which is supplied from a cylinder of liquid carbonic anhydride. The absorption liquid consists of equal parts of hydrogen peroxide and dilute (1:4) ammonia. The sulphuric acid which may be present in the hydrogen peroxide is previously precipitated *exactly* by the addition of barium chloride, the barium sulphate is allowed to settle, and the clear solution of peroxide siphoned off. *C* should be of such dimensions that 1 litre of gas may be drawn through it in 3.5 minutes.

10 grams of the iron or steel is introduced into *A*, the tap of *D* opened, and carbonic anhydride allowed to flow into the apparatus, which forces the hydrochloric acid from the funnel into the flask, after which the tap of *D* is again closed. In the case of steel, a small flame may be at once applied to the flask *A*; for iron 2—3 minutes should be allowed to elapse before heating. In about 5 minutes, the liquid is brought to boiling, and carbonic anhydride is then allowed to flow rapidly through the apparatus for 20 minutes.

The contents of *C* are now transferred to a beaker, and *C* is rinsed with 100 c.c. of water, the total volume now measuring 200 c.c. It is boiled for 2—3 minutes, 10 c.c. of dilute 1:1-hydrochloric acid added,

and boiled again to expel all carbonic anhydride. 10 c.c. of ammonia, sp. gr. 0.96, is added, together with 2 or 3 drops of methyl-orange, and if the liquid should still be acid, a little more ammonia is added, and the liquid is now neutralised very carefully with hydrochloric acid, so that the methyl-orange is not red, but only orange-coloured. It is now heated to boiling, 10 c.c. of barium nitrate solution (70 grams in 1000 c.c.) added, again heated to boiling, 10 c.c. of dilute hydrochloric acid added, and the precipitate allowed to settle while warm. After 15 minutes, it is collected, washed with hydrochloric acid and water, and the filter is placed in a porcelain crucible, charred in a muffle, and ignited for 15 minutes at a red heat. The whole determination lasts about two hours. The authors have found that the barium sulphate, if precipitated with barium nitrate from an exactly neutral liquid, and in the absence of metals, is very dense and easily filtered. The use of a mechanical stirrer still further shortens the time.

J. W. L.

Sulphuric Acid in Plastered and Natural Wines. By D. VITALI (*L'Orosi*, 14, 145—163).—Roos and Thomas (*Compt. rend.*, 111, 575) concluded that plastered wines contain normal potassium sulphate, because on adding ammonium acetate to the wine, precipitating the sulphuric acid with barium chloride, and igniting, the whole of the chlorine is found in the residue, whereas if an acid sulphate were present, some of the chlorine would be volatilised as ammonium chloride. The author finds, however, that under the above conditions ammonium chloride reacts with the potassium and calcium tartrates in the wine, so that the whole of the chlorine is fixed and remains in the ash.

The presence of acid sulphates in plastered wines may be demonstrated by treating them with some alkaloïd, such as quinidine, which is capable of extracting sulphuric acid from potassium hydrogen sulphate but has no action on the normal salt. The experiment is conducted as follows: an excess of freshly precipitated quinidine is added to the wine (3 parts) until its red colour is changed to a violet-blue, the whole briskly shaken, heated for a short time at 50—60°, chloroform (2 vols.), and sufficient absolute alcohol to dissolve it added, and then, without shaking, a volume of water about half the volume of the mixture is also added. After a time, the clear chloroform solution is drawn off, evaporated, and the residue tested for sulphuric acid. By the above method, the author has also succeeded in proving the presence of acid sulphates in the urine.

The presence of nitric acid in wine may also be detected by treating it with quinidine as above, evaporating the chloroform solution, treating the residue with water and potassium carbonate, to convert the nitric acid into potassium nitrate; this remains undissolved on treating the mass with alcohol and chloroform, and may be identified by the ordinary methods.

S. B. A. A.

Estimation of Small Quantities of Boric Acid. By F. PARMENTIER (*Compt. rend.*, 113, 41—43).—The method is based on the difference in the behaviour of helianthin and litmus or orceïn

towards boric acid and its salts. Yellow (alkaline) helianthin is not affected by boric acid or borates, whilst alkaline litmus, or, better, orcein, changes colour when the base is partially or entirely saturated. When the alkali is soda, the point is that at which the biborate is formed.

To estimate the boric acid in a mineral water, the residue, after removal of the silica, is dissolved in hydrochloric acid, and treated with ammonium nitrate and ammonia, to precipitate the iron, alumina, manganese, and arsenic and phosphoric acids. The filtrate is then acidified with hydrochloric acid, and divided into two equal portions, both of which are titrated with sodium carbonate, one with helianthin as indicator, the other with orcein.

In this way quantities of boric anhydride as minute as 1·8—2 milligrams per litre have been found in the waters of Royat.

Jx. W

Detection of Carbonic Oxide in Blood. By H. BERTIN-S. and J. MORENNE (Compt. rend., 113, 210—211).—See this vol. p. 1522.

Separation of Barium from Calcium. By R. FRESenius (*Zeit. anal. Chem.*, 30, 452—460).—When a solution containing much calcium with little barium, and feebly acidified with hydrochloric acid, is precipitated with a quantity of sulphuric acid only a little greater than is required to form barium sulphate with the barium present, the whole of the barium is not precipitated, although the precipitate retains some calcium, even after washing until calcium is no longer to be detected in the washings. If, on the other hand, six times as much sulphuric acid is added as corresponds with the barium present, the whole of the barium is indeed precipitated, but calcium is also thrown down, even when the amount of water present is nearly double that required to hold all the calcium sulphate in solution. In presence of a large quantity of hydrochloric acid, barium can be precipitated with approximate completeness only when much sulphuric acid is added. Thus, 400,000 parts of a liquid containing 1·2 per cent. of hydrogen chloride and 0·38 per cent. of sulphuric anhydride was required to dissolve 1 part of barium sulphate, whilst with the same strength of hydrochloric acid, but with sulphuric acid only slightly in excess of the barium present, the solubility was 1 part in 18,000. With a large excess of both hydrochloric and sulphuric acids, the separation of barium and calcium seems at first to be accurate, and is, in fact, better than with feebly acid liquids; it is, however, still imperfect. Diehl's method of separating the two bases, by digesting the mixed sulphates with a concentrated solution of sodium thiosulphate, gives approximately accurate results when the two sulphates have been precipitated separately and then mixed, though a little barium is lost, since barium sulphate is not absolutely insoluble in strong thiosulphate solution. When applied, however, to the sulphates precipitated simultaneously, a considerable amount of calcium sulphate remains undissolved. It is further to be noticed that from a thiosulphate solution, calcium cannot be completely precipitated by ammonium oxalate.

M. J. S.

Electrolytic Estimation of Metals as Amalgams. By G. VORTMANN (*Ber.*, 24, 2749—2765).—The metals are best obtained in the form of amalgams, by adding to the solution the corresponding salt to be examined, and a weighed quantity of mercuric chloride; in the case of acid solutions, pure precipitated mercuric oxide may be employed. At the commencement of the operation, a current giving 6—8 c.c. of oxyhydrogen gas per minute is employed; when the metal begins to be deposited, this is reduced to one giving 2—3 c.c., and, as the analysis proceeds, the current is gradually increased to its original strength. Mercury alone is quantitatively precipitated by electrolysis from solutions containing ammonium oxalate, ammonium tartrate, or alkaline sodium sulphide. After the deposition of mercury from solution in potassium iodide, it is needful to dissolve the iodine deposited on the positive electrode in soda and continue the electrolysis for an hour, or if the quantity of iodine is very small, it may be sufficient to wash the metal quickly with sodium sulphite solution. Mercury can also be deposited from an alkaline solution of potassium mercuric iodide; in this case, the metal should not be washed with alcohol, or particles will become detached.

Zinc is best deposited from solutions containing ammonium oxalate or from ammoniacal solutions; in the first case, not more than 2—3 parts of mercury should be added for 1 of zinc, but in the latter solution, the proportion should be at least 3 parts of mercury to 1 of zinc. As the platinum vessel is attacked during the operation, it is advisable either to deposit the zinc directly and not as an amalgam, or to employ a dish coated with copper or silver.

The determination of cadmium resembles that of zinc; on account of the sparing solubility of cadmium oxalate, it is best to employ an ammoniacal solution, unless the quantity of cadmium does not exceed 0.2—0.3 gram; there should be 4—6 parts of mercury to 1 of cadmium.

The deposition of lead from acid solutions is effected by dissolving the lead salt, together with mercuric chloride, in water, adding sodium acetate and a little concentrated potassium nitrite solution, the resulting precipitate being dissolved by the addition of acetic acid; the formation of any lead oxide towards the end of the operation can be prevented by the addition of small quantities of potassium nitrite. The lead amalgam is stable when dry, but in presence of moisture is quickly oxidised on exposure to air. Lead is also deposited quantitatively from alkaline solution; as the use of alcohol to dry the amalgam would cause loss, oxidation takes place, and consequently the results are somewhat high. The method affords, however, a ready means of separating lead from other metals, such as tin, antimony, or arsenic, and for this purpose it is convenient to employ an ammoniacal solution containing tartaric acid; when all the lead is deposited, the supernatant liquor is poured off, the amalgam dissolved in acid, and the solution treated as above described.

Bismuth is best determined in hydrochloric acid solution, the precipitation of basic salts being prevented by the addition of excess of potassium iodide, or by dilution with ethyl alcohol mixed with 2 parts of water. The second method is much better if bismuth is

present. The amalgam is stable, and may be heated at 90° in an air-bath without suffering any change. Should the bismuth be dissolved in nitric acid, not less than 4 parts of mercury to 1 of bismuth should be present, and it is necessary to add tartaric acid. The quantitative deposition of bismuth from ammoniacal solutions containing tartaric acid is unsatisfactory, but affords a useful means of separating it from tin, antimony, and arsenic.

Antimony is first oxidised to antimonious anhydride and then dissolved in soda and sodium sulphide; 2 parts of mercury to 1 of antimony must be present. The amalgam is very stable. As antimony is not precipitated from ammoniacal solutions containing ammonium tartrate, such a solution may be used to separate it from lead and other metals, whilst the first method enables it to be separated from tin.

No means have yet been discovered of determining arsenic in the form of its amalgam; during electrolysis, considerable quantities of arsenic hydride are evolved, and hitherto attempts to decompose this at the moment of its formation have proved fruitless. Arsenic amalgam undergoes no change on exposure to the air. J. B. T.

Antimony Pentasulphide: Separation of Arsenic and Antimony. By T. WILM (*Zeit. anal. Chem.*, 30, 428—446).—See this vol., p. 1432.

Detection and Separation of Metals of the Platinum Group in presence of other Metals. By A. JOLY and E. LEIDIG (*Compt. rend.*, 112, 1259—1261).—Osmium and ruthenium are removed in the form of volatile compounds, and iridium is removed by treatment with lead. A moderately dilute hydrochloric acid solution of the remaining metals is heated to about 60° and mixed with potassium nitrite. If much platinum is present, potassium platinochloride gradually separates as a crystalline precipitate quite free from other metals. After cooling and separation of this salt, the liquid is again heated and further quantities of nitrite added. Suddenly, and especially if the liquid is stirred, the crystalline double rhodium compound separates, carrying with it lead, bismuth, and tin, and small quantities of copper. If the liquid is allowed to cool, the separation of the rhodium becomes complete, provided that a moderately large quantity of potassium chloride is present. Should iron and copper be present, the addition of the nitrite is continued until the liquid becomes alkaline, and, on boiling, the iron and copper are precipitated, whilst platinum and palladium remain in solution. C. H. B.

Water Analysis. By C. LEPIERRE (*Bull. Soc. Chim.* [3], 5, 299—307).—A criticism of Boutron and Boudet's method for estimating hardness. The author describes the preparation of standard almond oil soap solution such that 1 c.c. corresponds with 1 milligram of dissolved calcium chloride, and records experiments and the calculated equivalent values for other calcium and magnesium compounds. Contrary to Wanklyn and Chapman, he states that magnesian waters do not require $1\frac{1}{2}$ times their calculated equivalent of soap solution for complete precipitation, but that the amounts required are the same as with calcium solutions of equivalent strength. It is only with solutions containing between 20 and 30 grams of calcium chloride (or

its equivalent in other calcium or magnesium salts) per litre that the soap solution required is directly proportional; both weaker and stronger solutions require relatively more soap solution. Tables are given for calcium salts and magnesium salts. T. G. N.

Detection of Cyanogen Compounds. By A. HILGER and K. TAMBA (*Zeit. anal. Chem.*, 30, 529; from *Mittheil. aus dem pharm. Inst. der Univers. Erlangen*, Heft ii).—Guaiacum-copper sulphate paper is a very untrustworthy test. It is much better to add to the suspected distillate in a basin a drop of freshly made guaiacum tincture and then a drop of copper sulphate. To detect cyanides in presence of ferrocyanides, the substance should be mixed with tartaric acid, then gradually made feebly alkaline with sodium carbonate, and treated with a current of carbonic anhydride in a distillation apparatus at a temperature not exceeding 60°, and the distillate tested. All metallic cyanogen compounds are decomposed by carbonic anhydride at 100°; but ferrocyanides and ferricyanides not below 80°, whilst the simple cyanides, including mercuric cyanide, are decomposed between 50° and 60°. M. J. S.

Detection of Turkish Geranium Essence in Oil of Roses. By G. PANAFOTOW (*Ber.*, 24, 2700—2701).—Oil of roses from South Bulgaria and Turkey is very often adulterated with Turkish geranium essence (*Indris Yaghi*); the presence of even traces of the latter can, however, be easily detected, since a mixture (2 to 3 drops) of the two oils gives a blue coloration on shaking with a solution of rosaniline previously decolorised with sulphurous anhydride, and then keeping for about two hours. Pure oil of roses gives a red coloration after shaking with the reagent and then keeping for about 24 hours.

When Turkish geranium essence is mixed with an equal quantity of concentrated sulphuric acid on a watch glass, a considerable development of heat occurs, and dense, white fumes, having a tarry odour, are evolved; on adding 95 per cent. alcohol to the brownish-red mixture, a yellow, fatty, flocculent substance is precipitated, and the solution, which is at first red, changes to yellow on keeping for some time. Oil of roses also gives, with concentrated sulphuric acid, a brownish-red solution, but, on the addition of alcohol, a clear, almost colourless solution is obtained. This difference in behaviour can also be made use of for the detection of geranium essence in oil of roses.

F. S. K.

Estimation of the Impurities in Alcohol by Röse's Method. By A. SCALA (*Gazzetta*, 21, 346—374).—The author gives a summary of our knowledge of the impurities present in commercial spirits, and then details experiments made to determine the trustworthiness of Röse's method of estimating the quantity of fusel oil present.

The experiments on the increase of volume experienced by chloroform, when agitated with spirit containing amyl alcohol or other ordinary impurities, are carried out in a stoppered glass cylinder of the form usually employed, having a capacity of 150 c.c., and a scale graduated in twentieths of a c.c. This is washed first with concentrated sulphuric acid, then with nitric acid, and finally with water, and

well dried; a little more than 20 c.c. of carefully purified chloroform is then put in, by means of a long-stemmed funnel, and the cylinder left in a bath until it has attained a temperature of 15°; the excess of chloroform is now taken out, leaving exactly 20 c.c. Meanwhile, pure alcohol has been diluted to a strength of 30 vols. per cent., the required quantity of impurity added, and the strength again reduced to 30 vols per cent. by addition of water or alcohol; 100 c.c. of this spirit is now put into the cylinder, together with 1 c.c. of sulphuric acid of density 1.286, all being kept at the standard temperature. After well agitating, the cylinder is returned to the bath, and the volume of the chloroform read off after 20 minutes.

The unit, from which the augmentation in volume of the chloroform is to be calculated, is obtained by performing the test with pure dilute alcohol of the standard strength, namely, 30 vols. per cent., and is 21.59 at the standard temperature. Consequently, this number must be subtracted from the volume obtained when operating with an impure spirit, in order to obtain the increase in volume due to the impurity.

A variation of ± 1 vol. per cent. in the strength of the alcohol employed is attended by a variation of ± 0.26 c.c. in the volume of chloroform obtained. A rise of temperature of 1° increases the volume of chloroform by 0.036 c.c. on the volume at 15°, but if the unit volume, that is to say, the volume which 20 c.c. of chloroform occupies after agitation with 100 c.c. of 30 vols. per cent. alcohol, be determined at temperatures other than 15°, the increase in volume due to fusel oil is practically a constant for other temperatures.

The results of an examination of the effect on the volume of the chloroform of other substances which might occur in spirits are embodied in the following table. The numbers give the increase in volume, over and above the unit volume, due to the presence of 1 c.c. of the corresponding substance in each 100 c.c. of 30 vols. per cent. spirit.

Name of substance.	Increase in volume.
Acetaldehyde	0.200 c.c.
Paraldehyde	1.000 "
Furfuraldehyde	0.601 "
Propyl alcohol	0.502 "
Normal butyl alcohol	1.161 "
Isobutyl alcohol	0.949 "
Amyl alcohol	1.507 "
Essence of aniseed	0.588 "
„ cinnamon	0.750 "

In the case of furfuraldehyde, there is seemingly a discrepancy between the values given in the table and in the text.

The increase in volume of the chloroform is directly proportional to the quantity of fusel oil present, and the author gives a table obtained by interpolation, from which the quantity present is deduced directly from that increase.

By previous distillation of the spirit with a few drops of potash, most of the acetaldehyde and furfuraldehyde is retained by the potash,

but the proportions of the other impurities present are practically unaltered by this treatment.

The author considers that this method for the determination of fusel oil is quite satisfactory if employed with the precautions detailed above, but that its indications are not to be depended on in the case of those liquors of which aromatic essences in quantity are essential constituents.

W. J. P.

Estimation of Phenol. By L. CARLÉ (*Compt. rend.*, 113, 139—141).—10 grams of pure phenol is dissolved in 1000 c.c. of water, and from this solutions are prepared containing 5.0, 3.0, 2.0, 1.0, 0.8, 0.6, 0.4, 0.2, and 0.1 gram of phenol per litre.

The phenol solution to be examined, if concentrated, is diluted with 10 times its volume of water. 25 c.c. of the solution is placed in a conical flask with 5 c.c. of nitric acid, and equal quantities of the standard solutions of phenol are treated in a similar manner, all the flasks being heated in the same water-bath for one or two hours. The intensity of the coloration produced is proportional to the quantity of phenol present. Greater accuracy is obtained if, after the action has ceased, the solutions are mixed with 20 c.c. of sodium hydroxide solution and diluted to exactly 50 c.c. The liquids are filtered, and compared by means of the colorimeter.

If alcohol is present, the action of heat must be continued until all the alcohol has been expelled; if the quantity of alcohol is considerable, the liquid must be diluted, in order to avoid the formation of ethyl nitrite. In the case of impure phenol, the heating must be continued until all tarry products are destroyed. As a rule, the termination of the reaction is indicated by the disappearance of the turbidity that was produced by the addition of the nitric acid.

C. H. B.

Estimation of Sugar and Tannin in Wines. By J. H. VOGEL (*Zeit. ang. Chem.*, 1891, 44—69).—The author has proved by several experiments that it is absolutely necessary to first remove the tannin and colouring matters before attempting to estimate the sugars by Fehling's solution. 25 c.c. of a 1 per cent. solution of tannin gave an amount of metallic copper corresponding with 0.91 per cent. of sugar. As the amount of tannin in Portuguese wines often is as high as 3 per cent., the importance of fully removing the tannin will be readily understood. After a short treatment with an insufficient amount of animal charcoal, the tannin is removed before the colouring matters are precipitated, and this fact enabled the author to prove that these colouring matters exercise a powerful reduction on the Fehling's solution, as the yield of copper became greater as the solution was more coloured. Their removal is best effected either with animal charcoal or basic lead acetate, but the author has made several important observations. As to the use of lead solution, 3 c.c. is supposed to be sufficient for 60 c.c. of Rhine wine, whilst for red wines, the amount must be doubled. But in the case of Portuguese wines, this amount is far too small, and the author has met with a sample which required three times its bulk of *liquor plumbi* before it was completely decolorised. The excess of lead must be removed, according to Barth, by sodium carbonate, but the lead

separates slowly, causing afterwards an increase in the weight of the copper precipitate, and unless the filtration has been very carefully effected, the sugar may come out from 0.2 to 2.2 per cent. too high, the error increasing with the amount of lead solution used. For wines rich in tannin and colouring matters, the charcoal process is the best. If, for this purpose, powdered purified animal charcoal is used, 25 grams of the charcoal will be found sufficient for 200 c.c. of wine. The time the charcoal is allowed to act varies from 15 to 60 minutes, according to the amount of colouring matters present. A little sugar is also absorbed by the charcoal, but the author, who has thoroughly investigated the matter, finds the amount never to exceed 0.3 per cent. under the most unfavourable conditions. In some cases, it is advisable to first dilute the sample with a known volume of water before attempting to decolorise with the charcoal. The author next investigated the two chief processes used for the estimation of the tannin. It must be borne in mind that this acid, as it occurs in wines, is not at all a definite chemical compound, and is not identical with gallo-tannic acid. The percentage found by analysis is therefore not the true one, but only expresses its equivalent in gallo-tannic acid. The process which was found to answer best was that of Löwenthal. According to this method, the solution containing the tannin is largely diluted with water, mixed with a definite quantity of solution of indigo carmine, containing sulphuric acid, and then titrated with a weak solution of potassium permanganate. Operating on a known quantity of tannin, and deducting the permanganate necessary for the oxidation of the indigo alone, the exact strength of the permanganate expressed in tannin is of course obtained.

In applying the process to wine, which of course contains many other organic matters, also oxidisable by permanganate, the author proceeds as follows: 20 c.c. of the sample is mixed with 2 litres of rainwater, 20 c.c. of solution of indigo-carmin (30 grams per litre), and 10 c.c. of sulphuric acid. A solution of potassium permanganate (1 : 1000) which has been carefully standardised is now run in until the liquid just loses its green, and changes to a bright-yellow, colour. To obtain the amount of permanganate absorbed by the organic matter, 50 c.c. of the sample is mixed with 100 c.c. of a solution of gelatin (1 : 1000), and 60 c.c. (= 20 c.c. of original sample) is filtered off, and again titrated. The difference between the two titrations represents the true amount of tannin. The permanganate absorbed by the excess of the gelatin varies but slightly, but may be put down as 0.2 c.c. As regards the process depending on the precipitation of the tannin by an ammoniacal solution of zinc acetate, previous to titration, the author found it to give results far too high and generally untrustworthy, even with solutions of pure tannic acid.

L. DE K.

Estimation of Cane Sugar in Soap. By J. A. WILSON (*Chem. News*, 64, 28—29).—The following method is found to be satisfactory:—A saturated solution of magnesium sulphate is gradually added and stirred into 10 grams of soap dissolved in 150 c.c. of water at 80°, and the magnesium soap is washed on a filter with hot water containing a small quantity of magnesium sulphate. The filtrate and washings,

after almost neutralising with dilute nitric acid, are evaporated to 40 c.c., and, when cool, acidified with dilute nitric acid, treated with a few drops of basic lead acetate and 2 c.c. of alumina emulsion, diluted to 50 c.c., and the solution polarised in a 200 mm. tube.

D. A. L.

Examination of Urine for Sugar. By E. LUTHER (*Chem. Centr.*, 1891, ii, 90—91; from *Centr. med. Wiss.*, 1891, 357—358).—The author has employed Molisch's furfuraldehyde reaction, as improved by Udranszky, for determining the sugar in urines (*Abstr.*, 1888, 863, 878).

He finds that a 0.1 per cent. solution of sugar gives the colour reaction and spectrum immediately; a 0.2 per cent. solution gives the coloration faintly after shaking several times, the violet colour passing later into a red.

One drop of the undiluted urine is first tested, and if it gives the furfuraldehyde reaction, it is diluted until the lowest limit, representing a 0.02 per cent. solution, of sugar is reached, from which the amount of sugar present may be calculated.

The naphthol test only indicates, however, the presence of carbohydrates generally, and, since gum is present in urines, the author makes a second determination after allowing the sugar to ferment with yeast, the difference between the total carbohydrates and the gum being grape sugar. In the case of diabetic urines, the amount of sugar, as determined by this method, is higher than if determined by either titration or polarisation. From a large number of determinations of sugar in urines, the author concludes that grape sugar is present in all urine, the amount found in that of adult persons being about 0.1 per cent., and varies according to the quality and quantity of the food, and depends also on the length of time which has elapsed since the meal. The total carbohydrates amount to 0.2 per cent. The kidneys possess the power of allowing sugar to pass in a slight degree, which is increased by those circumstances which cause an increase in the amount of sugar in the blood. It is for this reason that the urine of lying-in women contains relatively more milk sugar than usual.

J. W. L.

Babcock Method for Estimating Fat in Milk. By F. T. SHUTT (*Chem. News*, 64, 3—4).—In the author's hands, the Babcock method for estimating fat in milk yielded fairly accordant results in duplicate experiments; but, in comparison with gravimetric analysis, the results were somewhat low; the maximum deficit recorded is, however, 0.25 per cent. In applying the method, the sulphuric acid is added to, and well mixed with, the milk, and, while still hot, the mixture is centrifugalised in the machine, which is also kept hot with hot water. Hot water is then added, and the amount of fat noted immediately at the close of the operation.

D. A. L.

Reactions of Olive Oil. By G. DE NEGRI and G. FABRIS (*Chem. Centr.*, 1891, ii, 87—88).—After an exhaustive examination of a large number of samples of olive oil of known purity, the authors find (a) the iodine "number" is slightly higher for oils derived from mature than from immature olives, whilst the reverse is the case with regard

to the age of the oil; also, the mode of manufacture has an influence on this test. On the other hand, the locality of growth has no influence on the iodine test, whilst the variety of olive influences the iodine-absorbing quality of the oil, and the "number" rises to 88 in some cases. The specific gravity is almost constant, varying only from 0.916 to 0.918 at 15°. The free fatty acid of the oil melts at 24–27° and solidifies at 17–22°, the determinations being made with samples obtained by pressing the olive; the fatty acids of oil obtained by extracting the olives with carbon bisulphide or ether melt at 25–29° and solidify at 22°. The "saturation equivalent" (milligrams of KHO required to saponify 1 gram of oil) varies from 185 to 196, and is 190 for most samples. The temperature of a mixture of olive oil and concentrated sulphuric acid was nearly constant at 35°, the lowest reading being 32° and the highest 37°. The pure oil does not give any peculiar colorations with those reagents which are usually employed for distinguishing oils; those oils, however, which are obtained from immature olives, or which are extracted by carbon bisulphide, give colour reactions of an indefinite character

J. W. L.

Estimation of Fatty Matter in Turkey-red Oil (Oleine). By R. WILLIAMS (*Chem. News*, 64, 15–16).—The volumetric method, heating with dilute acid and some salt solution on the water-bath, adding more hot salt solution, and then reading the volume of fat when cold, gives results 2 to 4 per cent. too high, whereas low results are obtained by the Wilson method, in which the oil mixed with brine and hydrochloric acid is extracted twice with ether, the mixed extracts evaporated, and the residue dried by means of dry air, absolute alcohol, and heating. The author has obtained satisfactory results with the wax method in the following manner:—200 grains of the sample is warmed with 50 grains of 10 per cent. hydrochloric acid and 300 grains of saturated salt solution, warmed gently for a few minutes, 200 grains of wax added, and the whole heated until perfectly liquid. After cooling for some hours, the cake of wax is removed, washed with saturated salt solution, then with a little cold water, dried first with filter paper, then either over sulphuric acid in a desiccator or by heating not above 160° F. and stirring. The weight, less dish and wax, gives the quantity of fat.

D. A. L.

Lard and its Adulterations. By H. W. WILEY (*Zeit. anal. Chem.*, 30, 510–516; from *Foods and Food Adulterants*, Washington Government Printing Office, 1889).—The specific gravity of pure lard is about 0.89 at 40° and about 0.86 at 100°, referred to water of 4°. According to the part of the body from which the fat is taken, the melting point may vary from 35.1° to 44°, and the iodine absorption from 52.55 to 85.03 per cent. The chief adulterants are beef tallow and cotton-seed oil. Bechi's silver nitrate test, Maumené's sulphuric acid reaction (*Abstr.*, 1889, 319, 320), and the microscopic examination of the crystals from ethereal solution (*Abstr.*, 1890, 428) are all recommended. The author's method of determining the melting point of a fat is described, and the apparatus figured (compare *Abstr.*, 1888, 99).

M. J. S.

Estimation of Urea. By K. A. H. MÖRNER and J. Sjöqvist (*Chem. Centr.*, 1891, ii, 230—231, from *Centr. Physiol.*, 5, 150—152).—To 5 c.c. of the urine in a flask, 5 c.c. of a saturated solution of barium chloride containing 5 per cent. of barium hydroxide is added also 100 c.c. of ether-alcohol (2 parts of 97 per cent. alcohol to 1 part of ether), and the mixture is allowed to remain in the closed flask until the following day; the precipitate is filtered off and washed with ether-alcohol. The ether-alcohol is separated from the filtrate at a temperature of 55° (not exceeding 60°), by means of a current of air at low pressure being passed through the liquid. When the volume is reduced to 25 c.c., a little water and some magnesia are added, and the evaporation continued until the distillate shows no alkaline reaction. The residual liquid, measuring from 15—20 c.c., is treated with a few drops of concentrated sulphuric acid and evaporated on the water-bath, after which the nitrogen in it is determined by Kjeldahl's method and calculated into urea. J. W. L.

Reactions of Cocaine and of Ecgonine. By D. VITALI *L'Orosi*, 14, 1—19).—If a barely visible particle of cocaine is placed in a porcelain capsule, covered with 0.5 to 1 c.c. of concentrated sulphuric acid, stirred until solution is complete, and a quantity of potassium or sodium iodate or iodic acid twice or three times as great as that of the cocaine taken is added, and the whole gently heated with great care on the water-bath, the liquid soon exhibits striations of a bright green colour, which, on continued heating, changes to grass-green, and subsequently into blue; on raising the temperature, the liquid becomes violet, and violet fumes are evolved. This reaction is very sensitive, and is obtained very clearly with 0.00005 gram of the hydrochloride; with very careful working, 0.00002 gram of the base may be recognised. The action of sulphuric and iodic acids on a large number of alkaloids has been investigated by the author, and from the results, which are given at length, it appears that whilst many alkaloids, as for example, thebaine, atropine, chelidoneine, coridaine, &c., exhibit highly characteristic colour changes, only caffeine and theobromine give the same sequence of chromatic effects when the test is made as described for cocaine. If, however, the quantity of iodic acid used is not too small, the greenish or bluish-green coloration exhibited by these alkaloids is not followed by any violet coloration, as in the case of cocaine. Traces of benzoic acid behave with sulphuric and iodic acids exactly like cocaine, and the behaviour of the alkaloid is probably due to its decomposition by sulphuric acid with the formation of some benzoic acid. Ecgonine gives under the same conditions a yellow coloration, which quickly changes to bright red, and finally to brown.

On adding a drop or two of a dilute sulphuric acid solution of potassium permanganate (0.5 per cent.) to a little cocaine dissolved in a few c.c. of concentrated sulphuric acid, a violet coloration is obtained which disappears on agitation, and reappears on adding more of the reagent. With ecgonine, a yellow coloration is given by the first few drops of the reagent, and subsequent additions produce a violet coloration, which is more stable than that obtained with cocaine.

A solution of iodine in potassium iodide affords a ready means of distinguishing cocaine from ecgonine. With the former, a reddish-brown precipitate is formed, consisting of microscopic, perfectly spherical, black globules; ecgonine likewise yields a reddish-brown precipitate, which, however, becomes crystalline in a few minutes, forming microscopic tufts of reddish-yellow, rhombic tables or prisms. No crystallisation is obtained if the dilution of the solution is more than 500 to 1. Ecgonine may be recognised by this test in the extracts from animal remains; urine must, however, be tested directly by placing a drop on a glass slip, adding one or two drops of the reagent, allowing it to evaporate almost to dryness, and examining under the microscope. The urine must contain at least 1/600 of ecgonine. From further experiments made by the author, it appears that cocaine is not affected by prolonged contact with putrefying animal remains, and that, when taken internally, it is almost entirely decomposed within the system, only a very small proportion passing into the urine.

Ammonium Selenite as a Reagent for Alkaloids. By A. J. FERREIRA DA SILVA (*Compt. rend.*, 112, 1266—1268).—The reagent is prepared by dissolving 1 gram of ammonium selenite in 20 c.c. of concentrated sulphuric acid.

Atropine, no coloration. *Aconitine*, no immediate change; after 20 minutes, very slight rose coloration. *Berberine*, greenish-yellow coloration, becoming very brown, then rose at the edges and violet in the middle, and after half an hour wine-red, persisting for three hours. *Brucine*, rose or reddish coloration, becoming pale-orange; after half an hour, amber colour with no precipitate; no further change. *Caffeine*, no coloration; after three hours, reddish tint and slight precipitate. *Cinchonidine*, no reaction. *Cinchonine*, no reaction. *Cocaine*, no perceptible coloration or precipitate after half an hour; after three hours, same result as with caffeine. *Curarine*, slight violet coloration, becoming reddish after some time; no precipitate after three hours. *Delphine*, slightly reddish coloration, changing to violet-red; no precipitate after three hours. *Digitaline*, no immediate coloration; after half an hour, yellowish; after three hours, reddish precipitate. *Eserine*, lemon-yellow coloration, becoming orange; paler after three hours. *Morphine*, very bright greenish-blue coloration; after half an hour, yellowish-maroon, with no precipitate; after three hours, brown-maroon, with no precipitate. *Narcotine*, bluish coloration, becoming violet and afterwards reddish; after half an hour, beautiful reddish colour, and no precipitate; after three hours, slight red precipitate. *Narceine*, yellowish-green coloration, becoming brownish, and, after half an hour, reddish; distinct red precipitate after two or three hours. *Papaverine*, bluish coloration, becoming bottle-green, dull yellowish-green, blue-violet, and finally red; slight bluish precipitate. *Pilocarpine*, no reaction. *Solanine*, canary-yellow, changing to brown; after half an hour, a rose ring; after three hours, red-violet. *Saponine*, yellowish coloration, becoming reddish; indistinct reaction. *Senegine*, slight dull-yellow coloration; after three hours, reddish. *Veratrine*, indistinct yellowish

coloration, sometimes with a green tinge, becoming yellow after half an hour; after three hours, red precipitate and indistinct yellowish liquid.

The colorations and precipitates are not due merely to the reducing power of the alkaloids, as Lafon supposes, for narceine produces a much more rapid precipitation of selenium than does morphine, although the latter is the more powerful reducing agent of the two.

Extraction of the Colouring Matter of Wines. By L. HUGOUNENQ (*J. Pharm.* [5], 24, 51—53).—A 10 per cent. solution of tartaric acid is neutralised with a slight excess of ammonia; to this is added normal lead acetate until the lead precipitate just begins to be permanent. After a time, this solution is filtered and added to the wine, previously neutralised by ammonia, as long as a precipitate forms. This precipitate is washed, suspended in a small quantity of 80° alcohol, and a 15 per cent. solution of sulphuric acid added drop by drop, excess being avoided. The solution takes an intense red colour, and lead sulphate is precipitated, which is filtered off after some hours. To the alcoholic solution is added about 20 times its volume of water, when almost the whole of the colouring matter is precipitated; this is collected, washed, and dried at a low temperature. To purify the product, it is dissolved in alcohol, and evaporated in a vacuum over sulphuric acid. The colouring matter of berries and flowers used to falsify wine can also be isolated by this method.

J. T.

Method of Detecting Artificial Coloration in Wine. By G. PAPASOGLI (*L'Orosi*, 14, 37—47).—If a thin film of transparent, colourless gelatin is immersed in the sample of wine for 10 to 15 minutes, and dried by pressure between filter paper, it remains colourless if the wine is genuine, but acquires a distinctive tint if any artificial colouring matter is present. When the stained films are treated with sodium carbonate, stannous chloride, or copper acetate, they undergo further changes of colour by which the common dyes may be distinguished from each other. The presence of small quantities of coal-tar colours may be readily detected by this method, which, however, is less sensitive to colouring matters of vegetable origin. For the latter, the following method is proposed:—2 or 3 c.c. of a 10 per cent. solution of lead nitrate is added to 15 c.c. of the wine, the mixture filtered, and the precipitate on the filter covered with the solution of lead nitrate; when this has run through, it is treated on the filter with 6 to 8 c.c. of a saturated solution of borax. A turbid filtrate passes through, which yields a colourless solution on refiltration if the wine is either pure or only contains extract of logwood or brazilwood, or very small quantities of extract of hollyhock (*Althea rosea*) or of bilberry (*Vaccinium myrtillus*). An addition of 15 c.c. of the borax solution is also made to the wine filtered off from the lead nitrate; the liquid, after separation of the precipitate, remains colourless if the wine is pure, or only contains the colouring matters just mentioned.

Logwood and brazilwood are specially tested for by agitating 10 to

15 c.c. of wine with dilute sulphuric acid (2 c.c.) and manganese dioxide (4 grams), filtering, and treating the straw-coloured filtrate with stannous chloride. If the above-mentioned dyes are present, the liquid becomes red. The presence of the colouring matter of hollyhock or bilberry is detected by comparing the colour of a mixture of 10 c.c. of the sample and 90 c.c. of a solution of sodium hydrogen sulphite with that of 10 c.c. of a pure wine of the same depth of colour as the sample and 90 c.c. of sulphite. The presence of the adulteration is indicated by a diminution in the intensity of the colour. Full tables are given for the discrimination of the colour absorbed by the gelatin, and of the colours produced in the boracic liquids in cases of sophistication. S. B. A. A.

Assay of Indigo. By F. VOELLER (*Zeit. ung. Chem.*, 1891, 110—111).—Processes based on oxidation with potassium permanganate; hydrochloric acid and chloride of lime; sulphuric acid and potassium dichromate, &c., do not give satisfactory results, as commercial indigo usually contains other organic matters (oxalic acid has even been employed as an adulterant); besides it is a very difficult matter to properly notice the end-reaction when titrating. The same foreign matters also interfere with the accuracy of reduction processes, such as Pugh's, with ferrous sulphate and sodium hydroxide, or Fritzsche's, with glucose, alkali, and alcohol, where the object is to reduce the indigo-blue to indigo-white, and to finally reoxidise this to the blue compound. Berzelius found that, besides indigo-blue and some mineral matter, the commercial product contains three other substances, which he called indigo-gluten, indigo-red, and indigo-brown. The first, which is soluble in dilute acids, bears some resemblance to vegetable casein, and is precipitated from its solution by alcohol and tannin. The second, which is mostly met with in samples prepared by the lime process, is soluble in alkalis, whilst the third is soluble in hot alcohol. Berzelius' process for the assay of commercial indigo is to first extract the sample with hydrochloric or acetic acid, then with alkali, and finally with hot alcohol and water, when a fairly pure indigo-blue will be obtained. The author has improved the process by estimating the nitrogen in the purified product by Kjeldahl's method, and calculating from this the percentage of pure indigo-blue, by multiplying by the factor 9.36. After verifying the accuracy of the process on a sample of sublimed indigo, he analyses the crude product as follows:—The washings with acid, soda, alcohol, and hot water are performed in a perforated platinum crucible, closed with asbestos, and connected with a filter pump. The asbestos containing the indigo-blue is then boiled with sulphuric acid and a drop of mercury, and the ammonia so produced estimated as usual.

INDEX OF SUBJECTS.

ABSTRACTS. 1891.

And also to Transactions, 1891 (marked TRANS.); and to such papers as appeared in the Proceedings during the Session 1890—1891 (Nos. 87 to 100; Nov., 1890 to July, 1891), but not in Transactions (marked PROC.).

A.

Absorption of fat, 756, 849.
 — of fats in absence of bile, 593.
 — of light, measurement of, 965.
 — of mercury salicylate, 351.
 Absorption-plates of wood wool, 260.
Acacia tenerrima, alkaloid from, 336.
 Accumulator, chemistry of the, 514.
 Acetal, derivatives of, 540.
 Acetaldehyde, conversion of alcohol into, by "champignon du muguet," 854.
 — relation between the spectrometrical constants and chemical constitution of, 630.
 — trithio-, 1008, 1010.
 Acetamidochrysene, and its derivatives, 730.
 Acetamido- β -naphthoic acids, 78, 79.
 Acetamidopiperonylnitrile, ortho-, 706.
 Acetamidorthotoluquinoline, 328.
 Acetanilides, bromonitro-, 564.
 Acetanilidoglutaranil, β -, 742.
 Acetanilidoglutaranilic acid, β -, 742.
 Acetanilidoglutaric anhydride, β -, 742.
 Acetic acid, effect of, on respiratory changes, 344.
 — — vapour pressures and molecular volumes of, TRANS., 903.
 — fermentation, influence of artificial gastric juice on, 438.
 Acetoacetaldehyde, action of hydroxylamine on, 416.
 Acetoacetictetrahydroquinolide, 736.
 Acetobisnone, 551.
 Aceto-chloronaphthalide, tetrachlor-, 462.
 Acetomalani, 1221.
 Acetomalic- α -dinaphthalide, 1220.
 Acetomalic- β -naphthyl, 1221.
 Acetone, action of diazobenzene chloride on, 1449.

Acetone, action of dilute nitric acid on, 287.
 — action of sodium on, 1181.
 — action of zinc and ethyl chloracetate on, 169.
 — chlor-, action of ethyl benzoylsodacetate on, TRANS., 191.
 — crude, investigation of, 819.
 — derivatives of, 540.
 — detection of, in urine, 634.
 — estimation of, 370.
 — estimation of, in denaturated alcohol, 1142.
 — estimation of, in urine, 370.
 — isonitroso-, action of hydroxylamine on, 287.
 Acetonediacetic acid dilactone, 1337.
 Acetonedicarboxylic acid, 670.
 — — alkyl derivatives of, 678.
 — — condensation of, with phenols, 672.
 — — oxime of, 422.
 — — synthesis of citric acid from, 672.
 Acetonedithylmercaptole, chlor-, 568.
 Acetonephenanthraquinone, condensation of, TRANS., 105.
 Acetone-potash, 1183.
 Acetone-soda, 1183.
 Acetone-sodium, action of ethyl chloro-carbonate on, 1182.
 Acetonitrile, action of organic acids on, 409.
 — trichlor-, polymeride of, 1332.
 Acetylacetone, action of nitric acid on, 890.
 Acetoparatoluidide, action of chlorine on, 1466.
 Acetophenone, isonitroso-, action of hydroxylamine on, 288.
 — α -isonitroso-, configuration of, 1048.

- Acetophenone, oxidation of, 1364.
 Acetophenoneacetonedioxime, 1503.
 Acetophenonehydrazone, orthamido-, 1377.
 Acetophenoneoxime, orthamido-, 1376.
 Acetopropyl alcohol, oxime of, and its anhydride, TRANS., 866.
 Acetothienone, action of ethyl oxalate on, 550.
 Acetothiënoneoxalic acid, 550.
 Acetotoluidide, metaparanitrochlor-, 195.
 ——— parachlor-, 195.
 Acetoxime, compounds of, 1181.
 Acetylacetometamidobenzoic acid, *ac.*-, 1485.
 Acetylacrylic acid, 1185.
 ——— dibrom-, 427.
 Acetylaimidoethenylamidocarvacrol, 188.
 Acetylaimidoethenylamidothymol, 188.
 Acetylaimidonitrocresol, 308.
 Acetylaimidotoluic acid, 1095.
 Acetylanissaldoximes, α - and β -, 443.
 Acetylbenzaldoximes, α - and β -, 443.
 Acetylbenzeneazoparacresol, 1209.
 Acetylbenzeneazopseudocuminol, 1209.
 Acetylbenzenehydrazo- α -naphthol, 1211.
 Acetylbenzenehydrazoparacresol, 1209.
 Acetylbenzenehydrazopseudocuminol, 1209.
 Acetylbenzylthiocarbamide, TRANS., 408, 562.
 Acetylbromobenzene, 684.
 Acetyl- α -bromonaphthalene, 684.
 Acetyl- β -bromonaphthalene, 685.
 Acetylcarbamide, thermochemistry of, 1448.
 Acetylcannabinol, TRANS., 786, 790.
 ——— osazone of, TRANS., 795.
 ——— preparation of, from monochloroacetone, TRANS., 794.
 ——— reduction of, TRANS., 796.
 Acetylcannabinyl acetate, TRANS., 788.
 Acetylchloralimide, 1003.
 Acetylcystine, 750.
 Acetyldibenzylthiocarbamide, TRANS., 406.
 Acetyldigitogenin, 576.
 Acetyldimethoxygentisein, 1386.
 Acetyldimethylindole, 1502.
 Acetyldiphenylene oxide, 1234.
 Acetylene bromide, molecular refraction and dispersion of, TRANS., 295.
 ——— condensation of, by the silent discharge, 23.
 ——— diiodide, supposed isomeride of, 654.
 Acetyloxanthone ethyl ether, 1349.
 Acetylformylcamphor, 574.
 Acetylhydroxyhydrazobenzene, 1210.
 Acetylhydroxy- α -truxillic acid, β -, 1496.
 Acetylimidomethylene ethylene bisulphide, 894.
 Acetyliodobenzene, 684, 830.
 Acetylisocyanic acid, 282.
 Acetylmethahydroxybenzenylamidoxime, meta-, 699.
 Acetylmethahydroxybenzonitrile, 699.
 Acetylmethylindazole, [2' : 3'], 1377.
 Acetylmethylsindazole, [1' : 3'], 1376.
 Acetylmethylortho-xylidine, 1203.
 Acetylmethylloximidacetic acid, 445.
 Acetylnaphthylglycollic acid, β -, 729.
 Acetylorthamidacetophenoneoxime, 1377.
 Acetylorthamidobenzophenone, 1378.
 Acetylorthonitrobenzylparatoluidine, reduction of, 726.
 Acetylorthonitrohydroxyazobenzene, 1211.
 Acetylparachlorobenzophenones, 314.
 Acetylparahydroxybenzenylamidoxime, 700.
 Acetylparatolueneazophenol, 1210.
 Acetylparatoluenehydrazophenol, 1210.
 Acetylparatolyl phenyl ketoxime, β -, 68.
 Acetylpentachlorobutyric acid, dichlorobromo-, 691.
 ——— trichlor-, 691.
 Acetylphenylhydrazonophthalaldehydic acid, 1371.
 Acetylphenylsindazole, [1' : 3'], 1378.
 Acetylpropionyl- α - β -phenylhydrazacetoxime, 1116.
 Acetylpsudocumeneazophenol, 1210.
 Acetylpsudocumenehydrazophenol, 1211.
 Acetyltetrachlorometahydroxybenzoic acid, 710.
 Acetyltiophenaldoxime, β -, 444.
 Acetyltrichlorocrotonic acid, dichloro-, 690.
 Acetyltrimethylene, action of hydrogen bromide on, TRANS., 876.
 ——— hydrolysis of, TRANS., 876.
 ——— reduction of, TRANS., 874.
 Acetyltrimethylenecarboxylic acid, oxime of, TRANS., 867.
 ——— ——— preparation of, TRANS., 863.
 ——— ——— reduction of, TRANS., 870.
 Acetyltrimethyleneoxime, TRANS., 865.
 Acidimetric solutions, standardising, 959.
 Acidimetry, potassium iodate as original standard for, 614.
 Acids, aromatic carboxylic, new method of obtaining, 565.
 ——— ——— unsaturated, preparation of, 1225.
 ——— basicity of, deduced from their electrical conductivity, 631, 682.
 ——— hibasic, electrolytic synthesis of, 1192.

- Acids, bibasic, solid, relations of the heats of combustion of, to those of the gaseous hydrocarbons, 252.
- fatty, determination of the structure of, by bromination, 1189.
- free, estimation of, in fodder, 770.
- in butter, estimation of, 868.
- influence of, on gaseous metabolism, 345.
- synthesis of, in the animal organism, 757.
- thermochemistry of, 11.
- $\alpha\beta$ -halogenised, de-halogenisation of ethyl salts of, 1184.
- iodometric, estimation of, 360.
- isomeric organic, and their salts, electrical conductivities of, 375.
- ketonic, action of phenylhydrazine and hydroxylamine on, 711.
- β -ketonic, action of hydroxylamine on, 739.
- preparation of ethereal salts of, 1185.
- mineral, action of, on lactic and butyric fermentations, 488.
- molecular conductivity of, in various solvents, 1308.
- of the acetic series, vapour pressure of, 969.
- of the fumaric series, 1220.
- organic, action of ammonia on the ethereal salts of, TRANS., 743.
- action of nitriles on, 409.
- action of, on salivary digestion, 592.
- action of phosphorus trichloride on, 170.
- affinity (dissociation) constants of, 257.
- bibasic, thermochemistry of, 968.
- effect of, on the digestion of proteids, 751.
- heats of dissolution and solubility of, in various alcohols, 1314.
- isomeric, electrical conductivity of, 517.
- unsaturated, addition of the elements of alcohol to the ethereal salts of, TRANS., 468.
- intramolecular change in, 452.
- volatile fatty, amount of, in rancid butter, 130.
- Aconine, TRANS., 286.
- Aconitic acid, action of phosphorus pentachloride on, 178.
- synthesis of, 424.
- Aconitine, 91.
- aurochloride, TRANS., 278.
- Aconitine, crystalline, properties of, TRANS., 276.
- crystallographical characters of, TRANS., 288.
- effect of heat on, TRANS., 282.
- gold chloride, TRANS., 279.
- reaction for, 1562.
- specific rotation of, TRANS., 281.
- Aconitum napellus*, crystalline alkaloid of, TRANS., 271.
- Acetaldehyde, action of alcohol on, 285.
- Acridines, new class of, 219.
- Adhesion at the freezing point, 969.
- Adipomalic acid, 174, 175.
- Adonis, 1501.
- Adonis amurensis*, glucoside from, 1501.
- Affinity and magnetism, connection between, 1146.
- and partition coefficients in immiscible solvents, 1148.
- coefficients, determination of, 796.
- constants of organic acids, 257.
- of organic bases, 638, 1149.
- Aguilarite, 1327.
- Air and carbonic anhydride, compressibility of mixtures of, 258.
- and hydrogen, compressibility of mixtures of, 634.
- estimation of carbonic anhydride in, 1290.
- gravimetric composition of, 1416.
- Priestley's method of estimating oxygen in, 362.
- Air-pump, automatic mercury, 640.
- glass, 1414.
- Alanine, condensation of, with benzene-sulphonic chloride, 202.
- Albite from Pouzac, Hauts-Pyrénées, 408.
- from Sigterø, 1438.
- Albumin, behaviour of, when heated with water or acids under pressure, 1269.
- decomposition of, in fasting, 1524.
- detection of, in bacterial urines, 136.
- egg, action of glycerol on, 589.
- crystalline, 1122.
- free from ash, 477, 1268.
- effect of increased muscle activity on the decomposition of, 1524.
- formation of carbamide from, 95.
- Harnack's ash-free, 477, 1268.
- in urine, volumetric estimation of, 627.
- new test for, 136.
- optical estimation of, in urine, 1403.
- seat of the regeneration of, from peptone, 234.
- Albumins, action of alcohols and aldehydes on, 947.

- Albumoses, action of alcohols and aldehydes on, 947.
 — pathological significance of, 761.
 Alcaptonuria, 1128.
 Alcohol and water, solubility of some substances in a mixture of, 794.
 — compound of, with sodium bisulphide, 1170.
 — conversion of, into aldehyde by "champignon du muguet," 854.
 — crude, purification of, 997.
 — denaturised, estimation of acetone in, 1142.
 — detection and estimation of, in corpses, 118.
 — estimation of, by oxidation with potassium dichromate and sulphuric acid, *TRANS.*, 93.
 — estimation of the impurities in, by Rose's method, 1555.
 — influence of, on proteid metabolism, 1272.
 Alcohols, action of, on animals, 1393.
 — action of propaldehyde on, 284.
 — dihydric, derived from isobutaldehyde, 31.
 — estimation of, in brandy and spirits, 503.
 — fatty, action of iodine on, 656.
 — higher, in commercial spirits, origin of, 813.
 — production of, in fermentation, 411.
 — metallic derivatives of, 656.
 Aldehyde. See Acetaldehyde.
 Aldehyde-ammonia, action of, on animals, 1393.
 Aldehyde-blue, 1071.
 Aldehyde-green, 1070.
 — constitution of, 1072.
 Aldehydes, action of, on thioamides, 831.
 — action of zinc and ethyl chloracetate on, 169.
 — aromatic, and aromatic amines, condensation products of, 50.
 — behaviour of, with orthamidophenols, 1363.
 — compounds of camphor with, 1498.
 — estimation of, in brandy and spirits, 503.
 — Gayon's reaction for, 1142.
 — oximes of, 443.
 — potassium mercurio-iodide as a reagent for, 624.
 — thio-, isomerism of, 1008.
 — unsaturated, action of hydrocyanic acid on, 37.
 Aldehydobenzoic acid, meta-, 1346.
 — ortho-, action of orthodiamines on, 746.
 — para-, 1346.
 Aldoximes, action of nitric peroxide on, 316.
 — configuration of stereoisomeric, 439.
 Algarobilla, tannin of, 918.
 Alicyclic homology, 1097.
 Alizarin, α -amido-, 1077.
 — α -nitro-, 1077.
 Alizarin-blue, hydroxy-derivatives of, 1882.
 — oxidation of, 1240.
 Alizarin-blue-green, 1882.
 Alizarin-bordeaux, 935.
 Alizarinecyanin R, 935.
 Alizarin-green, 1883.
 — oxidation of, 1240.
 Alizarin-indigo-blue, 1883.
 Alizarinsulphonic acids, 934.
 Alkali, estimation of small quantities of, 1136.
 — halides and oxides of the heavy metals, action between, 1413.
 — hydroxides, detection of traces of, 364.
 — metals, spectra of the, 137.
 — salts, influence of the hydroxides on the solubility of, 1318.
 Alkalimetric solutions, standardising, 959.
 Alkalimetry, potassium iodate as original standard for, 614.
 Alkaline earths, estimation of the peroxides of, 245.
 Alkalis, iodometric estimation of, 360.
 Alkaloid, crystalline, of *Aconitum napellus*, *TRANS.*, 271.
 — formed in the cultivation of the swine fever bacillus, 476.
 — from *Chrysanthemum cinerariifolium*, 833.
 — from *Tylophora asthmatica*, 1260.
 — new, from *Conium maculatum*, 1119.
 Alkaloids, ammonium selenite as a reagent for, 1562.
 — detection and estimation of, in corpses, 119.
 — from plants growing in the Dutch Indies, 334.
 — from the roots of *Sanguinaria canadensis* and *Chelidonium majus*, 843.
 — from the seeds of *Delphinium staphisagria*, 842.
 — of *Belladonna*, 748.
 — of *Chelidonium majus*, 229, 843.
 — of *Corydalis cava*, 1266.
 — of *Sabadilla* seeds, 844.
 — of the areca nut, 94, 1520.
 — of the rhizome of *Veratrum album*, 87, 230.

- Alkaloids, total, estimation of, in cinchona bark, 1402.
- Alkanna root, detection of the colouring matter of, 372.
- Alkyl iodides, action of, on acetoacetates, 796.
- action of, on sodium derivatives of phenols and cresols, 796.
- Alkylallylsemithiocarbazides, conversion of, into isomeric bases, 548.
- Alkylammonium chlorides, dissymmetry and optical activity of, 1002.
- Alkyl-compounds of cadmium and magnesium, 682.
- Alkylisoxaloximes, additive compounds of, 1477.
- Alkylisophthalic acids, 1064.
- Alkylloxides of sodium, oxidation of, by atmospheric oxygen, 1332.
- preparation of, 657.
- Alkylpyridylammonium salts, reduction of, 1388.
- Alkylthiosinamines, conversion of, into isomeric bases, 548.
- Alkyltricarballic acids, synthesis of, 546.
- Allanite, 155.
- Allantoin, thermochemistry of, 1448.
- Allocinnamic acid, 832.
- condensation of, with phenols, 1484.
- Alloisomerism, 1184.
- Allomucic acid, 1198.
- Alloxan, thermochemistry of, 1448.
- Alloxantin, thermochemistry of, 1448.
- Alloxazine, 1341.
- Alloys, electrical resistance of, 5.
- melting point of certain, 648.
- new method of making, 805.
- ternary, 267, 1158.
- triple, of gold, cadmium, and tin, freezing points of, *TRANS.*, 936.
- Allyl alcohol, 1442.
- and methylbenzenes, condensation products of, 1462.
- fluoride, 409.
- tribromide, molecular refraction and dispersion of, *TRANS.*, 295.
- Allylacetic acid, dibromo-, 1453.
- molecular refraction and dispersion of, *TRANS.*, 295.

- *pantherina*, fat of, 1285.
- Amarantite from Chili, 274.
- Amarylline, 1122.
- Amaryllis belladonna*, alkaloid from, 1122.
- *formosissima*, alkaloid from, 1122.
- Amethylcamphophenolsulphonic acid, 324.
- Amides, acid, action of acid chlorides on, 57.

- Amides, aromatic, reduction of, 561.
 — physiological action of, 1282.
 Amidines, 60.
 Amido-acids, condensation products of, with benzenesulphonic chloride, 202.
 Amidoazo-compounds, cryoscopic experiments with, 1211.
 — ortho-, derivatives of, 839.
 Amido-derivatives, action of nitrous acid on, 292.
 Amido-group, displacement of halogens by, 36.
 — reagent for, 49.
 Amidosulphime dithiocarbamidodisulphinites, 557.
 Amidoximes, 538, 697.
 — sulphur derivatives of, 557.
 Amines, action of picric acid chloride on, in presence of alkali, TRANS., 714.
 — aromatic, and aromatic aldehydes, condensation products of, 50.
 — colour reactions of, 433.
 — nitration of, 692.
 — tertiary, action of phosphorus chloride on, 435.
 — action of selenyl chloride on, 696.
 — fatty, halogen derivatives of, 1472.
 — paraffinic, action of water on normal salts of, 797.
 — phenylsulphonic chloride, as a reagent for, 49.
 — secondary, action of, on imidoethers, 37.
 — aromatic, action of thionyl chloride on, 74.
 Amelidoacetic acid, 163.
 Ammonia, action of picric chloride on, TRANS., 715.
 — combination of, with chlorides, 643.
 — diffusion of, through water and through alcohol, 1147.
 — molecular refraction and dispersion of, in solution, TRANS., 595.
 Ammoniacal compounds, effect of, on hepatic glycogen, 1527.
 Ammonium acetate, magnetic rotatory power of solutions of, TRANS., 984.
 — chloride, dissociation of, 1415.
 — vapour density of, 1407, PROC., 1891, 2.
 — fluoroxymolybdates, 18.
 — formate, magnetic rotatory power of solutions of, TRANS., 982.
 — nitride, 525.
 — nitrite, catalytic decomposition of, 18.
 — nitroethane, TRANS., 413.
 — permolybdate, 988.
 Ammonium persulphate, TRANS., 777.
 — phosphate, magnetic rotatory power of solutions of, TRANS., 985.
 — pyrophosphate, 151.
 — nitrite, 809.
 — and nitrates as manures, 1545.
 — molecular refraction and dispersion of, in solution, TRANS., 595.
 — value of, as food for fermenting other plants, 1135.
 — theophosphate, 1238.
 — tin molybdate, normal, action of ammonium in solutions of, 271.
 — tungstovanadates, 18.
 Ammonium compounds, substituted, 736, 1217.
 — asymmetry of nitrogen in, PROC., 1891, 39.
 Amphibole, artificial formation of, 887.
 Amphibole from Habendorf, in Silesia, 23.
 Amyl alcohol, the fourth primary, 998.
 — formula, molecular refraction and dispersion of, TRANS., 295.
 Amylamine carbonyl chloroplatinite hydrate, 1163.
 Amylamines, 169.
 Amyl-derivatives, active, 281.
 Amylene, action of chlorine on, 534.
 — action of phosphorus pentachloride on, 534.
 — action of potassium cyanide on halogen derivatives of, 161.
 — halogen derivatives of, 533, 809.
 — hydrobromide, dissociation of, under low pressures, 970.
 — molecular refraction and dispersion of, TRANS., 295.
 — nitrate, decomposition of, with sodium ethoxide, 1005.
 — derivatives of, 1004.
 Amylenetriolamine, 1004.
 Amylenetriol- α -naphthylamine, 1005.
 Amylenetriolorthamidodiquinoline, 1005.
 Amylenes, action of bromine on, 810.
 Amylhexylquinoline, amido-, 1104.
 — nitro-, 1104.
 Amylphenothiosinamine, 549.
 Amylthiosinamine, 549.
 Amyrin, α - and β -, 165.
 — acetates, 165.
 — benzoates, 166.
 — brom- α -, and its acetate, 166.
 — brom- β -, and its acetate, 166.
 Analysis, elementary, by an electrothermal method, 621.
 — new potash apparatus for, 621.
 — microchemical mineral, reactions for, 760.

- Analysis, qualitative, dry reactions in, 959.
- Anethoil, action of light on, 1347.
- Angelie acid, action of bromine on, 39.
- Anhydroacetonephenanthraquinone, TRANS., 105.

 Auric sulphide, 526.
 Aurichlacte, 886.
 Auroauric sulphide, colloidal, 1162.
 Aurous sulphide, colloidal, 1162.
 Australene, change of rotation of, TRANS., 727.
 — hydrochloride, TRANS., 728.
 Autocatalysis, 1151.
 Axinite, 1329.
 — formula of, 1168.
 Azimidopara(para)toluidobenzoic acid, 306.
 Azines of the uric acid group, 1341.
 Azobenzene, dinitrochloro-, 1361.
 — dinitrometamido-, 554.
 — dinitroparamido-, 554.
 — orthonitroallometachloro-, 1361.
 — parabromo-, 211.
 — periodo-, 211.
 — trinitrochloro-, 1361.
 Azobenzenechlorobenzamide, 1037.
 Azobenzeneinduline, azido-, 1046.
 Azobenzene-metahydroxybenzoic acid, 1037.
 Azobenzene-nitro-para-chlorazobenzene, trinitronitroso-, 907.
 Azobenzene-para-chlorazobenzene, trinitronitroso-, 907.
 — trinitrosomito-, 907.
 Azobenzene-para-chlorophenylhydrazine, tetranitro-, 907.
 — trinitronitroso-, 907.
 Azobenzene-phenylhydrazine, trinitronitroso-, 907.
 Azobenzene- β -resorcylic acid, 1037.
 Azobenzene-salicylic acid, and its derivatives, 1036.
 Azo-derivatives, 1035.
 — of β -naphthylamine, TRANS., 372.
 Azomide, 56, 394, 524.
 — formation of, from dinitrotriazobenzene, 1473.
 Azonium bases, 1108, 1109.
 Azonium compounds, 945.
 Azo-orthotoluidine, ortho-, TRANS., 1016.
 Azoparamethoxytoluene, 1232.
 Azorthotoluquinoline, 328.
 Azosulphimecarbohydrosulphides, 557.
 Azotoline, 1046.
 Azoxazoles-carboxylic acid, 827.
 Azoximes, 538.
 Azoxybenzene, dinitro-para-chloro, 905.
 Azoxyorthotoluidine, para-, TRANS., 1016.
 Azoxyorthotoluquinoline, 328.
 Azoxyparamethoxytoluene, 1232.
 Azurite, crystallised, from Arizona, 992.

B.

Bacillus acidii levulactici, 660.
 — *ethaceticus*, fermentation of calcium glycerate by, TRANS., 81.
 — *frugi*, TRANS., 501.
 — of swine fever, ptomaines formed in the cultivation of, 476.
 — *pyocyaneus*, transformation and elimination of nitrogenous organic matter by, 1132, 1394.
 — tubercle, cultivation products of, 762.
 — *suaveolens*, 1284.
 Bacteria from flour, 1532.
 — living, osmotic experiments with, 1131.
 — substances which favour the development of, 100.
Bacterium glisorigenum, viscous material formed by, 1391.
 — souring, 603.
 Balance sheet of the Chemical Society from March 20, 1890, till March 19, 1891, TRANS., 448.
 — — of the Research Fund from March 20, 1890, till March 11, 1891, TRANS., 449.
 Balsams, excretion of, in the urine, 600.
 Barium chloride, combination of, with ammonia, 643.
 — — electrolysis of, 1421.
 — — double chloride and dithionate of, 16.
 — — estimation of, as sulphate, 1137.
 — — estimation of, in rock analysis, 768.
 — — fluoride, crystalline, preparation of, 1155.
 — — hydride, 1156.
 — — hydroxide, commercial, analysis of, 499.
 — — persulphate, TRANS., 779.
 — — rhodium nitrite, 809.
 — — salts, molecular refraction and dispersion of, in solution, TRANS., 595.
 — — — titration of, 115.
 — — separation of, from strontium, 110.
 — — — from calcium, 500, 1552.
 — — strontium and calcium, separation of, 111.
 — — subchloride, 1421.
 — — tungstovanadates, 18.
 — — zirconate, 1482.
 Barium-group, analysis of, 364.
 Barley, change in the nitrogenous substances in, during germination, 489.
 — — digestibility of, 595.
 — — germinating, influence of temperature on, TRANS., 664.
 — — non-nitrogenous extract-substance from, 957.

- Barytes from Rumelange, 1436.
 Basalt of the Stempel near Marburg, 1440.
 Basaltic rocks of Hessen, 1440.
 Base, new, from epichlorhydrin and phenylhydrazine, 582.
 Bases, action of acid chlorides on, in presence of alkalis, 295.
 ——— nitrogenous, in seeds, 490.
 ——— organic, formation of, by the decomposition of proteids in the vegetable organism, 756.
 ——— organic, action of acid chlorides on, in presence of alkalis, 181.
 ——— affinity of, 638, 1149.
 ——— endothermic and exothermic reactions of, 377.
 ——— new class of, 581.
 ——— primary and secondary, alkylation of, by potassium alkyl sulphates, 1118.
 ——— velocity coefficients of, 1413.
 Batteries, secondary, 3, 514, 777.
 Battery, copper oxide, 1405.
 ——— gas, 374.
 Beans, assimilation of nitrogen by, 1539.
 ——— digestibility of, 595.
 Beer, analysis of, 368.
 ——— non-nitrogenous extract-substance from, 957.
 Beeswax, analysis of, 131.
 ——— bleaching of, 625.
 ——— detection of paraffin in, 122.
 Beet, sugar-, experimental plots of, at Grignon, in 1890, 493.
 ——— gummy exudation from the, 284.
 Beetroot, economy of phosphoric acid in the growth of, 613.
 ——— loss of sugar in, 103.
 ——— seed, analysis of, 764.
 Behenic acid, heats of combustion and formation of, 11.
 Behenoic acid, heats of combustion and formation of, 11.
 Belladonna, alkaloids of, 748.
 Bellamarine, 1122.
 Benzalbenzamide, 194.
 Benzalcamphor, 1498.
 Benzaldehyde, action of, on phenylthiocarbimide, TRANS-, 67.
 ——— action of sulphur on, 1049.
 ——— and paranitrobenzyl cyanide, condensation of, 208.
 ——— condensation of, with phenols, 1234.
 ——— 2:4-dichloro-, and its derivatives, 450.
 ——— 2:5-dichloro-, and its derivatives, 450.
 ——— 3:4-dichloro-, and its derivatives, 450.
 Benzaldehyde, metachloro-, and its derivatives, 448.
 ——— metanitro-, condensation of, with quinaldine, 329.
 ——— products of condensation of, with phenol and resorcinol, 1346.
 ——— nitro-, and paranitrobenzyl cyanide, condensation of, 208.
 ——— nitrochloro-, 704.
 ——— orthochloro-, and its derivatives, 448.
 ——— orthonitrometachloro-, 1098.
 ——— parachloro-, and its derivatives, 449.
 ——— α -thio-, 1050.
 ——— β -thio-, 1050.
 ——— γ -thio-, 1049, 1050.
 Benzaldehydophenylhydrazone, metachloro-, 1098.
 Benzaldehydesulphonic acid, 720.
 Benzaldine, thio-, 1050.
 Benzaldoxime ethyl ethers, α - and β -, paranitro-, 1476, 1477.
 ——— methyl ethers, α - and β -, paranitro-, 1476, 1477.
 ——— β -paranitro-, 1035.
 Benzaldoximeorthocarboxylic anhydride, 1369.
 Benzaldoximes, action of phenylcarbamide on, 193.
 ——— action of phenylhydrazine on, 1361.
 ——— configuration of, 439.
 ——— constitution of, 1354.
 ——— isomeric paranitro-, 1476.
 Benzaldoximesulphonic acid, sodium salt of, 720.
 Benzalhydrazineacetic acid, 56.
 Benzamide, metanitroparamido-, 305.
 ——— nitramido-, 916.
 ——— orthamido-, formyl and oxalyl derivatives of, 908.
 ——— orthobromo-, 296.
 ——— parabromometanitro-, 305.
 ——— salicylate, 61.
 ——— sodium derivatives of, 58.
 Benzamidine, action of aldehydes on, 60.
 ——— action of, on the ethereal salts of aromatic orthohydroxy acids, 60.
 ——— salicylate, 60.
 Benzamidocacvaerol, amido-, 48.
 Benzamidopyruvic acid, 923.
 Benzamidothymol, amido-, 46.
 Benzanilide, metabromo-, 1237.
 ——— parabromometanitro-, 305.
 Benzaniline sulphite, 716.
 Benzene, action of camphoric anhydride on, 324.
 ——— action of chlorine on, in presence of sulphuric acid, 1196.
 ——— and its derivatives, physiological action of, 1279.

- Benzene and its halogen derivatives, molecular volumes of the saturated vapours of, *TRANS.*, 125.
- constitution of, 44, 632, 634, 897.
- α - and β -dibromodinitro-, 45.
- dinitrochloro-, 1031.
- effect of temperature on the refraction and dispersion of, *TRANS.*, 291.
- fluoro-, refraction and dispersion of, 774.
- halogen derivatives of, physiological action of, 1279.
- hexachloride, α - and β -modifications of, *TRANS.*, 165.
- hexachlorides, 1196.
- homologues of, physiological action of, 1280.
- iodation of, 1197.
- iodopentachloro-, 1197.
- metachloronitro-, sulphonation of, 1489.
- molecular refraction and dispersion of, *TRANS.*, 295.
- orthodibromo-, derivatives of, 44.
- parachloronitro-, sulphonation of, 1488.
- purity of, 684.
- relation between the spectrometric constants and chemical constitution of, 630.
- specific volume of, *TRANS.*, 44.
- structural formulæ of, 1343.
- symmetrical trisubstitution derivatives of, 1030.
- tribromodinitro-, action of sodium alkyl oxides and phenoxides on, 1024.
- tribromotrinitro-, action of sodium alkyl oxides and phenoxides on, 1024.
- unsymmetrical trinitro-, 429.
- Benzenazo- α -dimethylnaphthylamine, 470.
- Benzenazo- α -ethylnaphthylamine, 470.
- Benzenazomalonic acid, 922.
- Benzenazo- β -naphthylamine, action of aldehydes on, *TRANS.*, 380.
- action of nitric acid on, *TRANS.*, 379.
- orthonitro-, *TRANS.*, 378.
- Benzenazo- β -naphthylamines, nitro-, acetyl derivatives of, *TRANS.*, 375.
- formation of pseudazimides from, *TRANS.*, 378.
- Benzenazo-*ar*-octohydro- β -naphthaquinaldine, 1st-, 1513.
- Benzenazo-*ar*-octohydro- β -naphthaquinaldine, 2nd-, 1513.
- Benzenazo-*ar*-octohydro- β -naphthaquinoline, 1st-, 1512.
- Benzenazoline-*ar*-octohydro- α -naphthaquinoline, 1261.
- Benzenazo-ortho-xylylidine, 1205.
- Benzenazoparacresol, orthonitro-, 1210.
- Benzenazophenyl phosphate, 301.
- Benzenazophenylisoxalone, 468.
- Benzenazoquinoline, α -, 1509.
- Benzenazotetrahydro- α -naphthaquinoline, 1259.
- Benzenazotetrahydro- β -naphthaquinoline, 1st-, 1510.
- Benzenazotriphenylpyrazole, 319.
- Benzenediazobenzylanilide, dry decomposition of, 555.
- Benzenediazodimethylamide, preparation of, 556.
- Benzenediazopiperidine, dry decomposition of, 555.
- Benzenedisulphothiosulphonic anhydride, 925.
- Benzenehydrazoquinoline, α -, 1509.
- Benzenindulnes, 1046.
- Benzeno-nucleus, substitution of the anilido-group for halogen atoms in the, 304.
- Benzene, chloro-, thermochemistry of, 1311.
- nitro-, physiological action of, 1280, 1281.
- Benzenesulphinic acid, 203.
- acids, hydrolysis of ethereal of, 1229.
- Benzenesulphonates of aromatic radicle-, 568, 569.
- Benzenesulphone- β -alanine, 1459.
- Benzenesulphonic acid, action of iodine on the calcium salt of, 1226.
- — chloramido-, 1488.
- — chloronitro-, 1488.
- chloride, condensation products of amido-acids with, 202.
- iodide, 719.
- thioanhydride, 926.
- Benzenethiosulphonic thioanhydride, 925.
- Benzenoid acid chlorides, action of aluminium chloride on, *PROC.*, 1891, 70.
- derivatives, nitration of, *PROC.*, 1891, 89.
- Benzenylallylthiouramidoxime, 561.
- Benzenylamidine benzenyldioxytetrazotate, 1040.
- thiosulphate, 559.
- Benzenylamidodisulphine benzenylsulphimeditiocarbamate, 559.
- Benzenylamidoxime, action of carbon bisulphide on, 559.
- oxalate, 538.
- Benzenylamidoximeoxalic acid, 538.
- Benzenylazosulphimecarbanilide, 556, 560.
- Benzenylazosulphimecarbabisulphide, 559.
- Benzenylazosulphimecarbhydrosulphide, 559.
- Benzenylazosulphimecarbonitrosoanilide, 561.

- Benzenylazosulphimecarboparabromanilide, 561.
 Benzenylazosulphimecarbothioethyl ether, 560.
 Benzenylazoximecarboparatoluidide, 561.
 Benzenyldioxytetrazotic acid and its derivatives, 1040.
 ——— metanitro-, 1040
 ——— reduction of, 1041.
 Benzenylnaphthylenediamine, $\alpha\beta$ -, 1239.
 Benzenyloxytetrazotic acid, 1042.
 Benzenylparatolylthiouramidoxime, 558, 561.
 Benzenylphenylenediamine, 1378.
 Benzenyltetrazotic acid, 1042.
 Benzhydroxamic acid, constitution of, 697.
 Benzhydylamine, homologues of, 1479.
 Benzidine, oxidation of, in the animal organism, 1529.
 ——— synthesis of a diamidocarbazole from, 227.
 Benzidine-colouring matters, 1231.
 Benzidinedisulphonic acid, derivatives of, 929.
 Benzidinemetasulphonic acid, derivatives of, 313.
 ——— metadiamido-, 313.
 ——— metadinitro-, 313.
 Benzidylphthalaldehydic acid, 1370.
 Benzile, action of carbamide and thiocarbamide on, 725, 726.
 ——— and phenylorthophenylenediamine, base from, 1109.
 ——— condensation of, with orthamidodiphenylamine, 945.
 Benzileamidobenzamidothymol, 1363.
 Benziledioxime, action of phosphoric sulphide on, 1238.
 Benziledioximes, configuration of, 440.
 Benziledisulphonic acid, 721.
 Benzilemonoxime, β -, action of nascent hydrogen on, 726.
 Benzileoxime methyl ether, α -, 317.
 ——— γ -, 317.
 Benziloximes, ethers of, 317.
 Benzodichlorhydrin, 708.
 Benzoic acid, hydrogenation of, 1053, 1481.
 ——— metaparadiamido-, 303.
 ——— nitramido-, 916.
 ——— parabromometanitro-, derivatives of, 305.
 ——— parabromorthamido-, 565.
 ——— paranitrothiochloro-, 704.
 ——— acids, bromonitro-, 564.
 ——— anhydride, new mode of formation of, 565.
 ——— chloride, orthobromo-, 295.
 ——— fluoride, 200.
 ——— nitride, 56.
 Benzoicsulphinide, derivatives of, 1226.
 ——— parafluoro-, chloro-, bromo-, and iodo-, 1227.
 Benzoin, action of carbamide and thiocarbamide on, 725.
 Benzonitrile, action of, on organic acids, 409.
 ——— metabromo-, 296.
 ——— orthobromo-, 295.
 ——— orthobromometanitro-, 296.
 ——— parabromo-, 296.
 ——— parabromometanitro-, 296.
 Benzonitriles, bromo-, 295.
 ——— bromonitro-, 565.
 Benzophenone, action of hydrazine hydrate on, 1358.
 ——— benzyl ether, parachloro-, 314.
 ——— chloro-, oximes of, 445.
 ——— iodo-, paradiodo- and paradi-bromo-, 1236.
 ——— metabromo-, and its oximes, 1236.
 ——— metadibromo-, 315.
 ——— parabromo-, oximes of, 1235.
 ——— symmetrical paradichloro- and its oximes, 1237.
 Benzophenoneoxime, action of nitric peroxide on, 315.
 ——— action of phosphoric sulphide on, 1238.
 ——— amido-, 1378.
 ——— metadibromo-, 315.
 Benzophenoneoximes, parachloro-, 314.
 Benzophenones, halogenated oximes of, 314, 1236.
 Benzophenonesulphone, 1059.
 Benzophenyldihydroketometadiazine, 944.
 Benzopinacoline, β -, constitution of, 456.
 Benzotoluidine sulphite, 717.
 Benzoylacetalddehyde, action of hydroxylamine on, 451.
 Benzoylacetaldoxime, 451.
 Benzoylacetic acid and its derivatives, *TRANS*-, 996.
 Benzoylacetone methylimide, 1091.

 Benzylpropylene- ψ -thiocarbamide, *TRANS.*, 560.
 Benzylpropylnitramine, 168.
 Benzylpyridine and its derivatives, 90.
 Benzyltetrahydroquinoline, derivatives of, 89.
 Benzylthiocarbamide, 1474, *TRANS.*, 552.
 Benzylthiocarbimide, 1214.
 — preparation of, *TRANS.*, 407, 552.
 Berberine, 332.
 — reaction for, 1561.
 Beryllium, atomic weight of, 881.
 — carbonates, 151.
 — hydride, 1155.
 — minerals from Colorado, 530.
 — oxide, reduction of, with magnesium, 1155.
 — phosphates, 151.
 Betaine in seeds, 490.
 Betaines of pyridine bases, 941.
 Bidiethylazimethylene, 1355.
 Bidimethylazimethylene, 1355.
 Bidiphenylazimethylene, 1359.
 Bignamide, 1180.
 Bile, absorption of fats in the absence of, 593.
 — action of, on pancreatic digestion, 96.
 — constituents, detection of, in urine, 135.
 — electrolysis and putrefaction of, 591.
 — human, 598.
 — influence of alkalis on the secretion and composition of, 950.
 — influence of, on emulsification, 948.
 — influence of, on the fat-splitting properties of pancreatic juice, 948.
 — oxyhæmoglobin in, 599.
 — transformation of hæmoglobin in, 482.
 Bimethylethylazimethylene, 1355.
 Bimethylhexylazimethylene, 1355.
 Bimethylphenylazimethylene, 1355.
 Bimethylpropylazimethylene, 1355.
 Biogenesis of hydrogen sulphide, 102.
 Biophen, 551.
 Biotite from Gailbach, 1437.
 — from Miask, 531.
 Birch-wood tar, phenol of, 432.
 Bismuth, action of nitrosyl chloride on, *TRANS.*, 662.
 — atomic weight of, 271, 525, 1324.
 — bromide, 1161.
 — commercial, composition of, 1324.
 — conditions of action of nitric acid, 525.
 — effect of various metals on the freezing point of, *Proc.*, 1890, 159.
 Bismuth, electrical resistance of, 515.
 — electrolytic estimation of, as amalgam, 1553.
 — influence of temperature and state of aggregation on the behaviour of, in the magnetic field, 779.
 — metallurgy of, 1161.
 — minerals from Gladhammar, 20.
 — oxyiodide, 19.
 — salicylate, preparation of, 1366.
 — thermal dilatation of liquid, near its melting point, 518.
 Bismuthinite, seleniferous, 1328.
 Bismuth-silver-zinc alloys, 1158.
 Bismuth-tin-zinc alloys, 1158.
 Bismuth-zinc alloys, 1158.
 Bisparatolylmethylpyrazolone, *TRANS.*, 341.
 Bisphenylmethylpyrazolone, *TRANS.*, 339.
 Black ash, estimation of total soda, available soda, and free total lime in, 497.
 Bleaching of cotton by hydrogen peroxide, 1447.
 Bleaching-powder, technical valuation of, 615.
 — titration of, with hydrogen peroxide, 246.
 Bloedite from Hall, in Tyrol, 648.
 — from Tarapaca, 1436.
 Blood, action of leech extract on, 482.
 — alkalimetry of the, 1398.
 — alkalinity of the, after large doses of sodium sulphate, 341.
 — and salt solution, transfusion of mixtures of, 347.
 — arterial and venous, amount of dry residue and fat in, 347.
 — chemical theory of the coagulation of, 596.
 — corpuscles, action of various organic compounds on, 602.
 — destruction of sugar in, 596.
 — detection of carbonic oxide in, 496, 1522.
 — effect of medicines, especially of valerian extract, on the destruction of sugar in, 754.
 — effect of peptone on the clotting of, 481.
 — estimation of inorganic salts in small quantities of, 619.
 — estimation of sugar in, 248, 504, 1399.
 — estimation of the alkalinity of, 348.
 — estimation of the oxygen in, 845.
 — glycolysis in the, 1528.
 — human, influence of acids and alkalis on the alkalinity of, 1528.
 — in a case of melanotic sarcoma, 484.

- Blood in chyluria, 1124.
 — in leucocythæmia, 1124.
 — increase in the hæmoglobin in, at great altitudes, 751.
 — isolation of the glycolytic ferment of, 755.
 — new method of estimating the specific gravity of, 1123.
 — of animals at great altitudes, oxygen in the, 753.
 — of vertebrates, relative alkalinity of, 348.
 — pressure, action of paraffinic nitrites on, 1270.
 — relation of dextrose to the proteids of the, 350.
 — specific gravity of, 1527.
 — specific gravity of, in disease, 761.
 — specific quantities of oxygen in, 344.
 — vessels, action of nicotine on, 96.
 Boiling point under any pressure, calculation of, 1406.
 — points, determination of, with small amounts of substances, 873, 1146.
 — — determination of, with the platinum thermometer, 251.
 — — molecular volumes and chemical characters of liquids, relations between, 379.
 — — high temperature, pressure variations of, 9.
Boletus luridus, fat of, 1285.
 Bonds, double, theory of, 1320.
 Bone-meal, amount of fat in, 106.
 — composition of, 105.
 Bones, influence of acid mineral salts on the composition of, 848, 1525.
 — of aged rabbits, 1275.
 — of normal and rachitic children, inorganic constituents of, 847.
 Borate, new, from Stassfurt, 528.
 Borax, action of, in photographic developers, 139.
 Boric acid, detection and estimation of, in milk and cream, 619.
 — — estimation of small quantities of, 1551.
 — — solutions, electrical conductivity of, in presence of dulcitol, 251.
 — anhydride, action of organic halogen compounds on, 281.
 Boron bromide, action of hydriodic acid on, 980.
 — bromodides, 980.
 — electrolysis of fused compounds of, 1321.
 — hydride, 979.
 — nitride, action of alcohols on, 1003.
 — phosphide, 1418.
 — selenite, 981.
 — sulphide, 981.
 Boron, triiodide, 979.
 Boyle's law, applied to salts in solution *TRANS.*, 351.
 Brain, influence of sodium chloride or the chemical composition of the, 1274.
 Brandy, analysis of, 503.
 Brassidic acid, heats of combustion and formation of, 11.
 Bread, estimation of alumina in, 114.
 — fermentation, 1532.
 Breunerie, from Hall, in Tyrol, 648.
 Brewer's pitch, estimation examination of, 512.
 Brine-spring at Lautenthal, 652.
 Bromanil, 1028.
 Bromanilic acid, 1028.
 Bromic and hydriodic acids, influence of mineral acids on the velocity of the reaction between, 144.
 Bromides, chlorides, and iodides, detection of, 495.
 — detection of chlorine and chlorides in presence of, 1288.
 Bromine, chlorine, and iodine, detection of, in presence of one another, 361.
 — direct estimation of, in mixtures of alkali bromides and iodides, 361.
 Bromoform, molecular refraction and dispersion of, *TRANS.*, 295.
 Brookite from Beura, Ossola, 527.
 Brucine, distillation of, with lime and with potash, 87.
 — reaction for, 1562.
 Burette-float for opaque liquids, 1288.
 Butallylcarbindimethylamine, 1506.
 Butallylmethylcarbinamine, 1507.
 Butallylmethylcarbindimethylamine, 1507.
 Butallylmethylcarbintrimethylammonium salts, 1507.
 Butane, tertiary nitro-, 653.
 Butenylanisole, para-, molecular refraction and dispersion of, *TRANS.*, 295.
 Butenylbenzene, β -, molecular refraction and dispersion of, *TRANS.*, 295.
 Butoxybenzaldehyde, ortho-, 1051.
 Butter, analysis of, 506, 869.
 — and margarin, discrimination of, 130.
 — cocoa-, iodine number for, 869.
 — detection of margarin in, 1300.
 — estimation of soluble and insoluble fatty acids in, 868.
 — estimation of water in, 1300.
 — "oily," 603.
 — examination of, 1300.
 — new method of testing the purity of, 868.
 — rancid, amount of volatile fatty acids in, 130.

- Butter-fat, 757.
 — composition of, 507, 508.
 — optical analysis of, 1401.
 Butter-fats, composition of, 849.
 Butters, optical analysis of, 130.
 Butyl nitrate, normal primary, 168.
 — secondary, 164.
 — sulphides, occurrence of, in Ohio petroleum, 1173.
 Butylamine, tertiary, 654.
 Butylamines, normal, 662.
 Butylbenzene, parabromo-, 899.
 — parabromo- $\alpha\beta$ -dibromo-, 899.
 Butylcarbinol, tertiary, attempt to prepare, 1172.
 Butylethylbenzene, tertiary, 1466.
 Butylmetaxylene, tertiary, 1465.
 Butyltoluene, tertiary, amido- and nitro-derivatives of, 1464, 1465.
 — and its derivatives, 1464.
 Butyric acid, oximido-, salts of, 740.
 — fermentation, action of mineral acids on, 488.
 Butyrolin, 891.
 Butyrolactone- γ -carboxylic acid, 481.
 Butyryl- α -naphthol, 448.
 Bye-laws, alteration in, TRANS., 451.

C.

- Cactæ, simultaneous evolution of oxygen and carbonic anhydride by, 856.
 Cadmium, action of ethyl iodide on, 682.
 — action of nitrosyl chloride on, TRANS., 657.
 — alkyl compounds of, 682.
 — and copper, separation of, 1188.
 — atomic weight of, 390, 399.
 — dimethyl, 682.
 — dipropyl, 683.
 — effect of various metals on the freezing point of, PROC., 1890, 150.
 — electrolytic estimation of, as amalgam, 1553.
 — electrolytic separation of, from manganese, 1140.
 — estimation of, as sulphide, 112.
 — estimation of, in the products of zinc manufacture and in calamine, 112.
 — gold and tin, freezing point of triple alloys of, TRANS., 930.
 — methoxide, 682.
 — selenites, 262.
 — spectrum of, 1, 965.
 Cassium, spectrum of, 137.
 Caffeidine and its salts, 331.
 Caffeine, estimation of, 1, 408.
 — estimation of, in tea, 372.
 — reaction for, 1562.

- Calamine containing lead, estimation of zinc carbonate and silicate in, 863.
 — estimation of cadmium in, 112.
 Calcium, barium, and strontium, separation of, 111.
 — carbonate, action of metallic salts on, 995.
 — chloride, densities of solutions of, PROC., 1891, 105.
 — freezing points of solutions of, PROC., 1891, 105.
 — heat of dissolution of, PROC., 1891, 105.
 — fluoride, crystalline, preparation of, 1155.
 — glycerate (active), crystalline form of, TRANS., 233.
 — fermentation of, by the *Bacillus ethaceticus*, TRANS., 81.
 — hydride, 1156.
 — α -naphthylglycocine, 39.
 — orthotolylglycocine, 39.
 — oxalate in plants, 857.
 — phosphate, mono-, action of acetates on, 1422.
 — action of di- and tricalcium phosphates on, 880.
 — preparation of crystalline, 1421.
 — salts, magnetic rotation of, PROC., 1890, 142.
 — molecular refraction and dispersion of, in solution, TRANS., 595.
 — separation of barium from, 500, 1552.
 — silicozirconate, 1432.
 — sulphate, influence of, on nitrification of, 1543.
 — zirconate, 1432.
 Calorimetric bomb, use of, in determining the heat of combustion of coal, 520.
 — data, 907.
 Camphene, 1082.
 — action of phosphoric chloride on, TRANS., 652.
 — oxidation of, TRANS., 649.
 — preparation of, TRANS., 648.
 Camphenes, oloninic, 540.
 Campheno-series, thermochemistry of, 1818.
 Camphoric acid, TRANS., 649.
 Camphols, influence of solvents on the rotatory powers of, 575.
 Camphopyric acid, TRANS., 650.
 — anhydride, TRANS., 650.
 Camphor, action of ethyl formate on, 574.
 — and its derivatives, molecular refraction and dispersion of, in solution, TRANS., 591.

- Camphor, estimation of, 131.
 — hygroscopic behaviour of, 1497.
 — phenolic acid from, 324.
 — sulphonic derivatives of, TRANS., 966.
 Camphoric anhydride, action of, on benzene, 324.
 Camphorquinone, hydrazone of, 575.
 Camphors, bromo-, preparation of, TRANS., 968.
 — chloro-, preparation of, TRANS., 976.
 — compounds of, with aldehydes, 1498.
 — general account of the, 1078.
 Camphor-series, new compounds of, 1086.
 Camphorsulphonic acid, α -bromo-, and its salts, TRANS., 971.
 — β -bromo-, salts of, TRANS., 975.
 — α -chloro-, salts of, TRANS., 977.
 — β -chloro-, derivatives of, TRANS., 978.
 — chloride, α -bromo-, TRANS., 974.
 — α -chloro-, TRANS., 978.
 Camphosulphophenols, pyrogenic conversion of, into ordinary phenols, 1088.
 Cancer, analyses of healthy and altered tissues in cases of, 851.
 Cantharic acid, preparation of, 1243.
 Cantharidinallylimide, 1243.
 Cantharidinamylimide, 1243.
 Cantharidinimide, 1243.
 Cantharidinmethyylimide, 1243.
 Cantharidin- α -naphthylimide, 1243.
 Cantharidinphenylimide, 1243.
 Capillarity and electrical conductivity, analogy between, 1408.
 — effect of concentration on, 1408.
 — in homologous series, 1409.
 Capillary constants of organic substances in aqueous solution, 1408.
 Caprylacapramidoxime, 538.
 Caprylene, complete chlorination of, 811.
 Carbamide, estimation of, 759.
 — formation of, by the decomposition of arginine, 1521.
 — formation of, from albumin, 95.
 — methylene derivatives, 1339.
 — preparation of, 160.
 — thio-, constitution of, 548.
 Carbamidoethylphthalimide, β -seleno-, 1216.
 Carbamidometaphenylcarboxylic acid, 304.
 Carbamidopropylphthalimide, γ -seleno-, 1216.
 Carbamidothionaphthol bisulphide, 1049.
 Carbamidothionaphthol methyl thio-ether, 1049.
 — thio-, 1048.
 Carbamidothiophenol, thio-, 1048.
 Carbaminesulphinide, 1064.
 Carbanilamidothiophenol, 1049.
 Carbanilido- α -paranitrobenzaloxime, 1476.
 Carbanilido- β -paranitrobenzaloxime, 1476.
 Carbanilidophenylhydroxycarbamide, 1222.
 Carbazole, 570.
 — diamido-, synthesis of, from benzidine, 227.
 — nitro-, 570.
 — oxidation of, in the organism, 1529.
 — synthesis of, 571.
 Carbazole-derivatives, synthesis of, 834.
 Carbimidoacetic acid, thio-, 179.
 Carbimidoamidobenzoyl, properties of, 910.
 Carbimidoethylphthalimide, thio-, 1216.
 Carbinols, paramido-, 695.
 Carbocinnamylidithiocarbamic acid, ortho-, 199.
 Carbodimides, aromatic, action of orthodiazines on, 1468.
 Carbohemoglobins, β -, γ -, and δ -, 348.
 Carbohydrates, formation and migration of, in leaves, 763.
 — in the urine, 1392.
 — influence of, on proteid metabolism, 846.
 Carbolic acid, red, colouring matter of, 1198.
 — disinfecting powders, analysis of, 124.
 Carbon bisulphide, effect of temperature on the refraction and dispersion of, TRANS., 291.
 — purification of, 1417.
 — dichloride, molecular refraction and dispersion of, TRANS., 295.
 — hydroxide, 266.
 — new form of, 265.
 — of spiegeleisen, 646.
 — tetrachloride, molecular refraction and dispersion of, TRANS., 295.
 — specific volume of, TRANS., 43, 45.
 — thermochemistry of, 1311.
 — vapour pressures and molecular volumes of, TRANS., 911.
 — tetriodide, 1420.
 Carbon-atoms, mechanical determination of the arrangement of, in organic compounds, 1441.
 — singly bound, the relative motion of, 583.
 Carbon-chains, closed, formation of, 655.

- Carbon-chains, closed, synthetical formation of, TRANS., 853.
- Carbon-compounds, liquid, relation between viscosity and chemical constitution, 380.
- Carbonic anhydride, action of magnesium on, 801.
- and air, compressibility of mixtures of, 253.
- and oxygen, simultaneous evolution of, by *Cactæ*, 856.
- dissociation of, 143.
- estimation of, 1291.
- free and combined, estimation of, in mineral waters, 862.
- in air, estimation of, 1290.
- influence of temperature on the production of, by germinating barley, TRANS., 664.
- liquid, use of, for the rapid filtration and sterilisation of organic liquids, 854.
- solid, electrical phenomena developed in the formation of, 777.
- Carbonic oxide, absorption of, by earth, 16.
- action of heat on, 801.
- action of magnesium on, 801.
- compounds of, with iron, TRANS., 1090.
- detection of, in blood, 496, 1522.
- reaction for, 801.
- volatile compound of iron with, TRANS., 601.
- Carbonyl bromoplatinite, 1164, TRANS. 603.
- chloroplatinite, 1162.
- hydrochloride, 1162.
- chloroplatinites, TRANS., 598.

 Citramalic acid, constitution of, 1455.
 Citrazinic acid, action of heat on, 940.
 Citrene, thermochemistry of, 1315.
 Citric acid, a normal constituent of milk, 1276.
 — action of phosphorus pentachloride on, 178.
 — deflection and estimation of, in milk, 1276.
 — estimation of, in plants, 129.
 — origin of, in milk, 1276.
 — synthesis of, 178.
 — synthesis of, from acetonedicarboxylic acid, 672.
 Citronellal-phosphoric acid, 286.
 Citronellaldehyde, 285.
 Clark's test, modification of, 116.
 Clinoclone from Chester, Pennsylvania, and Brewster, New York, 531.
 Clotting of blood and lymph, effect of peptone on, 481.
 Clover land, effect of artificial manuring on, 492.
 Coagulation, 338.
 — intravascular, 953.
 — of proteids by heat, 1521.
 — action of salts on, 954.
 — of the blood, chemical theory of, 596.
 Coal, estimation of sulphur in, 1137.
 — use of the calorimetric bomb for determining the heat of combustion of, 520.
 Coal-tar, indene and cinnamene in, 205.
 Cobalt and nickel, separation and estimation of, 1139.

- Cobalt and nickel, separation of iron from, 1139.
 — dioxide, 1429.
 — electrolytic separation of gold from, 1396.
 — oxalates, electrolysis of, 1189.
 — refraction and dispersion of, 373.
 — salts, oxidation of, by electrolysis, TRANS., 760.
 — selenites, 262.
 — volumetric estimation of, 620.
 Cobaltamine salts, action of hydrogen sulphide on, 272.
 Cobaltic ammonium oxalate, TRANS., 769.
 — nitrate, TRANS., 770.
 — sulphate, TRANS., 768.
 Coca leaves, Javanese, alkaloid from, 1265.
 Cocaine chromate, 585.
 — mercurchloride, 585.
 — physiological action of, 487.
 — reactions of, 134, 1561, 1562.
 Cochineal-carmin, 378.
 Cocoa-butter, iodine number for, 869.
 Coconuts, milk of ripe and unripe, 764.
 Cohenite, 27.
 Cohesion, molecular, effect of concentration on, 1409.
 Colchicine, detection of, in corpses, 135.
 — estimation of, in colchicum seeds, 512.
 Colloidal solutions, nature of, 1412.
 — substances, cryoscopic investigation of, 145.
 Columbite from Delaware Co., Pennsylvania, 1168.
 — from the Black Hills, South Dakota, 886, 1329.
 Combustion, slow, of gaseous mixtures, 1153.
 Compressibility of hot water, 634.
 — of liquids and gases, 378.
 — of mixtures of air and carbonic anhydride, 253.
 — of mixtures of air and hydrogen, 634.
 Comptonite, altered, from Vesuvius, 23.
 Condensation in mineral chemistry, 258.
 Conductivity. See Electrical conductivity.
 Conduransterin, 1387.
 Conglutin, decomposition products of, 590.
 Conine, detection of, in a case of poisoning, 871.
Conium maculatum, new alkaloid from, 1119.
 Connellite, 157.
 Copper, action of nitrosyl chloride on, TRANS., 658.
 — and cadmium, separation of, 1138.
 — and its alloys, electrical resistance of, 5.
 — arsenates, 644.
 — atomic weight of, 806.
 — compounds, effect of, on plants, 491.
 — conditions of action of nitric acid on, 525.
 — detection of traces of, in distilled water, 620.
 — diphenyl, 1198.
 — electrolytic separation of gold from, 1396.
 — estimation of sulphur in, 362.
 — hydrides, 1422.
 — lead potassium nitrite, 1157.
 — phosphates, 1423.
 — piperilbiguanidine, 839.
 — potassium chloride and its solutions, vapour pressure of, 783.
 — pyrites, crystals of, 273.
 — salts, basic, action of water on, 1423.
 — selenites, 262.
 — separation of, from arsenic by the electric current, 114.
 — sulphate solutions, very dilute, determination of the electrical conductivity of, 905.
 — vapour pressure of, 782.
 — volumetric estimation of, 112.
 Coriander oil, 540.
 Coriandrol, 540.
 Cork cells and suberin, 465.
 Corpses, detection and estimation of organic and inorganic poisons in, 117.
 — detection of colchicine in, 135.
 Corydaline, 1266.
Corydalis cava, alkaloids of, 1266.
 Cotarnine, physiological activity of, 762.
 Coto bark, hydrocotoin from, 578.
 Cotton, bleaching of, by hydrogen peroxide, 1447.
 — dyeing, 662.
 — oil, analysis of, 130.
 Coumalin, 1460.
 Coumalinic acid, and its derivatives, 1457.
 Coumarin, metanido-, preparation of, 918.
 — metanitro-, 918.
 Coumarone, 506.
 — various reactions of, 455.
 Cows, composition of the milk of, during early and late periods of lactation, 97.

- Cows, hill-bred, amount of fat and dry matter in the milk of, 1275.
- Cream, detection and estimation of boric acid in, 619.
- the souring of, 603.
- Cresol, amidodinitro-, 309.
- amidometa-, 187.
- ethyl ether, dinitrometa-, 187.
- — trinitrometa-, 187.
- Cresolcinnamic acid, meta-, 320.
- — ortho-, 320.
- — para-, 320.
- Cresolglycollic acid, meta-, 320.
- Cresols, nitrometa-, 187.
- Cresotic acid, amidometa-, 309.
- — amidortho-, 308.
- acids, occurrence of, in artificial salicylic acid, 454.
- Cresotodichlorhydrin, para-, 708.
- Cresoxyethylamine, para-, 552.
- Cresoxyethylaniline, 552.
- Cresoxyethylcarbamide, para-, 552.
- Cresoxyethylphthalamic acid, 552.
- Cresoxyethylphthalamide, dinitro-, 552.
- para-, 552.
- methylphenylcarbamate, para-, 1215.
- Cresyl diphenylcarbamate, para-, 1215.
- glycidyl ether, para-, 1199.
- Critical data of liquids and their chemical constitution, relation between, 380.
- point, molecular conductivity at the, 1411.
- state of liquids, data for, 969.
- temperatures and pressures, determination of, 779.
- Crotalaria retusa* and *C. striata*, alkaloid from, 335.
- Crotonaldehyde, action of, on alcohol, 285.
- Crotonic acids, β -chloro-, 170.
- — sulphonic derivatives of, 203.
- Cruciferae, localisation of active principles in the seeds of, 490.
- Cryohydrates of mixtures of salts, 398.
- Cryolite, artificial, 806.
- Cryoscopic behaviour of aqueous cane sugar solutions, 972.
- experiments, 1211.
- investigation of colloidal substances, 145.
- method for determining molecular weights, 389.
- observations, 1411.
- Cryoscopy of dilute solutions, 971.
- Crystalline liquids, 249.
- Crystals, explanation of the optical activity of, 513.
- Cumalene, 675.
- Cumene, dinitroso-, 298.
- — paradiamido-, 298.
- — paradinitro-, 298.
- Cumene-series, change of propyl into isopropyl in the, 45.
- Cumenylacrylic acid, orthochloro-, 69.
- — orthobromo-, 69.
- Cumenylpropionic acid, constitution of, 69.
- — orthochloro-, 69.
- Cumic acid, bromonitro-derivatives of, 1055.
- — derivatives of, 1055.
- — orthamidometabromo-, 1056.
- Cumidoethylphthalamide, ψ -, 1203.
- Cuminalcamphor, 1498.
- Cuminalcamphor, 1498.
- Cumobenzyl alcohol, 1352.
- Cumobenzylamine, 1352.
- Cuprammonium bromides, 399.
- Cupresine, conversion of, into quinine, 1121.
- — metallic derivatives of, 474.
- Curare, physiological action of, 487.
- Curarine, reaction for, 1562.
- Current juice, fermentation of, 1539.
- Currants, red and black, colouring matters of, 1539.
- Cyanacetacetates, γ -, and their chlorimido-derivatives, 171.
- Cyanacetophenone, 451.
- Cyanisonitrosoacetic acid, 1184.
- Cyanobenzal chloride, meta-, 1341.
- — ortho-, 1460.
- — para-, 1344.
- Cyanobenzaldehyde, meta-, 1345.
- — para-, 1346.
- Cyanobenzyl bromide, ortho-, 1461.
- — chloride, meta-, 1344.
- — — ortho-, 1460.
- — cyanide, meta-, 1344.
- — diselenide, ortho-, 1161.
- — methyl selenide, ortho-, 1461.
- — selenocyanate, ortho-, 1460.
- — selenomercaptan, ortho-, 1460.
- Cyanobenzylphthalamide, meta-, 1345.
- Cyanocamphor, action of, on sodium phenoxide and naphthoxide, 464.
- — action of sodium benzyloxide on, 463.
- — derivatives of, 1490.
- Cyanocinnamic acid, ortho-, 1462.
- Cyanogen compounds, detection of, 1555.
- — estimation of, in coal-gas, 367.
- Cyanonitrosoacetic acid, 897.
- Cyanonitrosobutyric acid, 418.
- Cyanopalmitic acid, 821.
- Cyano- π -phenylosotriazole, 1114.
- Cyanostearic acid, α -, 1451.
- Cyanotriphenylmethane, ortho-, 1461.
- Cyanuracetic acid, 163.
- Cymene, 688, 897.
- — action of chromyl dichloride on, 1020.

- Cymene, constitution of, 686, 1344.
 — nature of the propyl group in, 686.
 — oxidation of, with chromyl chloride, 898.
 Cymene-derivatives, constitution of, 46.
 Cymenes, dibromo-, 1200, 1201.
 — dibromodiamido-, 1200, 1201.
 — dibromodinitro-, 1200, 1201.
 Cymenesulphonic acids, nitro-, 1066.
 Cymoquinols, dibromo-, 1200, 1201.
 Cymoquinones, dibromo-, 1200, 1201.
 Cymyl benzenesulphonate, 569.
 — ethyl ketone, para-, 1223.
 — methyl ketone, 199.
 — propyl ketone, para-, 1223.
 Cymylacetamide, para-, 199.
 Cymylacetic acid, para-, 200.
 Cymylcarboxylic acid, para-, 564.
 Cymylethylcarbinol, para-, 1223.
 Cymylglycollic acid, para-, 199.
 Cymylglyoxylic acid, para-, 199.
 Cymylmethylcarbinol, 199.
 Cymylpropylcarbinol, para-, 1223.
Cyrtosperma, hydrocyanic acid in the fruit of, 338.
 Cystin in pancreatic digestion, 235.
 Cystinuria and diamines, 350.
 Cysts, hydatid, liquids from, 97.
 — ovarian, analysis of liquids from, 851.
 Cytisine, 231, 946.
 — and its derivatives, 587, 750.
 — and ulexine, differences between, 334.
 — detection of, 947.
Cytisus laburnum, nitrogen assimilation of, 1588, 1586.

D.

 Diisobutylamine ethyl oxalate, 284.
 — oxalate, action of amines on, 377.
 Diisobutylglycollic acid, 891.
 Diisobutylpimelic acid, TRANS., 843.
 Diisobutylsulphonodimethylmethane, 180.
 Diisobutylsulphonemethane, 181.
 Diisopropylbenzene and its derivatives, 184.
 Diisopropylcarbinol, properties of, 889.
 Diisopropylcarbinyl acetate, properties of, 889.
 Diisopropylnitramine, 168.
 Diisopropylpimelic acid, TRANS., 840.
 Diisopropylsulphonediethylmethane, 180.
 Diisovaleryl, 890.
 Diketodihydropentene, tetrachloro-, 691.
 Diketohexamethylene, heptachlorometa-, 690.
 Diketohexene, hexachlorortho-, action of phosphoric chloride on, 819.
 — behaviour of, on heating, 819.
 Diketones, α -, transformation of, in alkaline solution, 335.
 Diketones, β -, action of hydroxylamine on, 739.
 Dilactylic acid, 177.
 Dilatation, thermal, of liquid bismuth near its melting point, 518.
 Dimethacrylic acid from isovaleric acid, 1011.
 Dimethamidobenzamide, 910.
 Dimethoxydimethylbenzidine, 1231.
 Dimethoxygentisine, 1386.
 Dimethoxymetaldolone, ortho-, 1232.
 Dimethoxyphenylglyoxylic hydrazonic, 711.
 Dimethyl barium phosphate, 1015.
 — $\Delta_{1,4}$ -dihydroterephthalate, heats of combustion and formation of, 376.
 — dipropyl glycol, TRANS., 875.
 — fumaroid-hexahydroterephthalate, heats of combustion and formation of, 376.
 — α -sulphaminephthalate, 1063.
 — terephthalate, heats of combustion and formation of, 376.
 — Δ_1 -tetrahydroterephthalate, heats of combustion and formation of, 376.
 Dimethylacetylcaproic acid, $\alpha\alpha'$ -, TRANS., 570, 584.
 Dimethylalloxazine, 1342.
 Dimethylamido- α -naphthaphenazine, α -, 471.
 Dimethylamido- α -naphthatoiazine, α -, 471.
 Dimethylaniline, derivatives of, 457.
 — reaction of oxyalkyl derivatives of, 693.
 Dimethylanilineazobenzylpiperidine, 80.
 Dimethylazethane, 1355.
 Dimethylbuldrazimethylene, 1356.
 Dimethylbromodinitroresorcinol, 1025.
 Dimethylcarbazole, 835, 1491.
 — diamido-, 834.
 Dimethyldiacetylpentane, $\alpha\alpha'$ -, TRANS., 570, 587.
 — dioxime of, TRANS., 588.
 Dimethyldiamidochlorothoxyquinone, 904.

- Dimethyldiamidophenyltolylmethane, *paranitro*-, 727.
 Dimethyldibromoheptamethylene, *TRANS.*, 223.
 Dimethyldicumylmethane, 1463.
 Dimethyldiethyldiamidodiphenyltolylmethane, *paranitro*-, 728.
 Dimethyldihydroxyheptamethylene, action of hydroxylamine on, *TRANS.*, 221.
 — action of phenylhydrazine on, *TRANS.*, 221.
 — condensation product of, *TRANS.*, 228.
 — constitution of, *TRANS.*, 221.
 — preparation of, *TRANS.*, 217.
 — sodium derivative of, *TRANS.*, 220.
 — synthesis of, *TRANS.*, 214.
 Dimethyl- $\alpha\alpha'$ -dimethylpyrrolidylammonium chloride, 1508.
 Dimethyldinitroresorcinol, 1025.
 Dimethyldipyridyl, $\alpha\alpha'$ -, 80.
 Dimethyldithioamide, 1008.
 Dimethylethoxybenzidine, 213.
 Dimethylglutamic acid, symmetrical, 1015.
 — and trimethylsuccinic acid, relative properties of, 669.
 — acids, 1016.
 Dimethylglyoxime peroxide, 816.
 Dimethylheptamethylene, *TRANS.*, 227.
 — diacetate, *TRANS.*, 225.
 — glycol, *TRANS.*, 217.
 Dimethylhomogentisic acid, 1129.
 Dimethylhydroxyiodoheptamethylene, *TRANS.*, 224.
 Dimethylimidothiazoline, 1516.
 Dimethylindigo, synthesis of, 722.
 Dimethyl lactamidine hydrochloride, 63.
 Dimethylmetaxyloquinol, 210.
 Dimethyl- α -methylpyrrolidylammonium salts, 1506.
 Dimethylnaphthasaurhodine, 471.
 Dimethylresorcinol, 1347.
 — dimethyl ether, 1347.
 Dimethylorthanisidine, nitro-derivatives of, 1081.
 — reactions of, 694.
 Dimethylorthophthalylididextroecgonine, 476.
 Dimethylortho-xylylidine, 1205.
 Dimethylortho-xyloquinol, 210.
 Dimethylloximidocaproic acid, *TRANS.*, 586.
 Dimethylparatoluquinoline, $\alpha\beta$ -. oxidation of, 1095.
 Dimethylparaxyloquinol, 210.
 Dimethylpentanetetra-carboxylic acid, *TRANS.*, 830.
 Dimethylphenanthroline, 1105.
 Dimethyl- α -phenylosotriazole, 1115.
 Dimethylphenylpyrazolesulphonic acid, 1107.
 Dimethylpimelic acid, $\alpha\alpha'$ -, *TRANS.*, 570, 577, 587, 832.
 Dimethyl- α -pipecolylammonium iodide, 1508.
 Dimethylpiperazine, γ -, 1333.
 Dimethylpiperidine, behaviour of, towards hydrogen chloride, 1506.
 Dimethylpyridine, $\alpha\alpha'$ -, *TRANS.*, 177.
 — oxidation of, *TRANS.*, 178.
 Dimethylpyridone, $\alpha\alpha'$ -, *TRANS.*, 177.
 Dimethylquinol, bromo-, 209.
 Dimethylquinoline, oxidation of, 1096.
 Dimethylquinoxalinemetacarboxylic acid, 303.
 Dimethylsafranine hydrochloride, 1205.
 Dimethylsuccinic acid, an isomeride of, 290.
 — acids, bromination of, 1191.
 — — substituted, 829.
 — — synthesis of, 1193.
 Dimethyltetramethylenediamine, $\alpha\beta$ -, 1503.
 Dimethylthiazole, $\beta\mu$ -, 222.
 Dimethylthiazole- β -carboxylic acid, $\alpha\mu$ -, 224.
 Dimethyltolualloxazine, 1342.
 Dimethyltriamidodiphenyltolylmethane, 727.
 Dimethyltribromonitroresorcinol, 1026.
 Dimethyluracil, imido-, 1007.
 Di- α -naphtholbenzylidenesulphonic acid, barium salt of, 721.
 Dinaphthyl bisulphide, 1:3-diamido-, 573.
 — ketone, β -, boiling point of, 1240.
 — picrates, 216.
 Dinaphthylamine, β -, boiling point of, 1240.
 Dinaphthylene oxide, β -, new method of preparation of, *TRANS.*, 1096.
 — — nitro-, *TRANS.*, 1100.
 — — tetrabromo-, *TRANS.*, 1100.
 — — tetranitro-, *TRANS.*, 1100.
 Dinaphthylene-oxide-tetrasulphonic acid, constitution of, *TRANS.*, 1099.
 Dinicotinic acid, $\alpha\alpha'$ -dichloro-, 940.
 Dinitro-compounds, reaction for, 685.
 Dioptase from the French Congo, 617.
Diospyros virginiana, crystalline principle from the bark of, 324.
 Dioxymethylenophenylglyoxylic hydrazone, 711.
 Dioxymethylenequinaldine, 705.
 Dioxypheazine, 944.
 Dioxyquinones, action of, on ortho-diamines, 944.
 Dioxytetrazotic acids, 1038.

- Dipentene, 1083.
 — dihydrobromide, action of bromine on, 1242.
 Diphenol, 930.
 Diphenoldisulphonic acid, 930.
 Diphenoxypropylamine, γ -, 1467.
 Diphenyl dicyanide, 60.
 — orthodiamido-, 570.
 — orthodinitro- 570.
 — oxidation of, in the animal organism, 1529.
 Diphenylacetaldoxime, 1070.
 Diphenylacetylene dibenzoate, 931.
 Diphenylacetyltoluylenediamine, 694.
 Diphenylamidomethylenephénylorthophényleneguanidine, 1469.
 Diphenyl- μ -amidothiazole, $\alpha\beta$ -, 222.
 Diphenyl- μ -amidoxazole, $\alpha\beta$ -, 725.
 Diphenylamine, action of picric chloride on, TRANS., 716.
 — amidochloro-, 299.
 — oxidation of, in the organism, 1529.
 Diphenyl-bases, 211.
 Diphenylbiguanide, β -, 1180.
 Diphenylbihydrazimethylene, 1357.
 Diphenylbromodinitroresorcinol, 1026.
 Diphenylcarbazole, 1212.
 Diphenylchloroformamide, compounds from, 1214.
 Diphenyl-derivatives from alkylquinols, 209.
 Diphenyldiamidohydroxybenzene, 191.
 Diphenyldiethylene and its derivatives, 76.
 Diphenyldihydroquinoxaline, 747.
 Diphenyldimethylazimethylene, 1359.
 Diphenyldinitromethane, 315.
 Diphenyldipyridazine, 1502.
 Diphenyldisulphine, metalinitro-, 567.
 Diphenyldisulphonic acid, amido-, 930.
 — — and its derivatives, 930.
 — — bromamido-, 929.
 Diphenylene oxide, 1234.
 — — diamido-, 1234.
 Diphenylenemethane sulphide, 1049.
 Diphenylenemethanesulphone, 1059.
 Diphenyletho- $\alpha\beta$ -dihydronaphthaquin-oxaline [1:3], 1514.
 Diphenylethonaphthazonium hydroxide, 1110.
 Diphenylethylidene, 296.
 Diphenylfurazan, 1237.
 Diphenylglyoxime peroxide, 316.
 Diphenylhydrazobenzyldienesulphonic acid, sodium salt of, 720.
 Diphenylhydrazonaphthalaldehyde acid, 1870.
 Diphenylhydroxyethylamine, 726.
 Diphenylhydroxytriketone, 1048.
 Diphenylimidothiazoline, 1517.
 Diphenyl- β -hydrochloride, iodo-, 211.
 Diphenylisosuccinic acid, TRANS., 731.
 — — preparation of, TRANS., 732.
 Diphenylketazine, 1359.
 Diphenylmaleanil, 71.
 Diphenylmaleic anhydride, 71.
 Diphenylmethane, bromo-, preparation of, TRANS., 731.
 — — oxidation of, in the organism, 1529.
 Diphenylmethylcinnamaldiazimethylene, 1360.
 Diphenylmethylenebenzaldazine, 1359.
 Diphenylmethylenecinnamaldazine, 1359.
 Diphenylmethylenehydrazine, 1358.
 Diphenylmethylenetetrazone, 1359.
 Diphenylmethylphenylazimethylene, 1360.
 Diphenyl- μ -methylthiazole, $\alpha\beta$ -, 222.
 Diphenylnaphthotriazine, and its derivatives, TRANS., 681.
 Diphenyl- β -naphthylamine, diamido-, 301.
 Diphenyloxycyanidine, 59.
 Diphenyl-4:5-phenylpyrrolidone, 3-, TRANS., 146.
 Diphenyl-4:5-phenylpyrrolone, 3-, TRANS., 144.
 Diphenylpropane, $\alpha\beta$ -, 207.
 Diphenylpropionic acid, β -, TRANS., 731.
 — — — preparation of, TRANS., 734.
 Diphenylpropyl alcohol, TRANS., 1009.
 Diphenylpyridone, 458.
 Diphenylpyridonecarboxylic acid, 458.
 Diphenylpyrone, 2:6-, 458.
 Diphenylpyronecarboxylic acid, 458.
 Diphenylquinoxalinemetacarboxylic acid, 303.
 Diphenylsuccinanil, 72.
 Diphenylsuccinanilic acid, 72.
 Diphenylsuccinic acids, 71.
 — anhydrides, 72.
 Diphenylsulphideorthocarboxylic acid, 1058.
 Diphenylsulphonamic acid, ammonium salt of, 569.
 Diphenylsulphone- β -thiophenylpropane, $\alpha\beta$ -, 1068.
 Diphenylthiazole, μ -, 221.
 Diphenylthiocarbamide, action of acetic acid on, TRANS., 329.
 — — action of water on, TRANS., 323.
 — — symmetrical, action of acetic anhydride on, TRANS., 396.
 Diphenyltolyltoluidihydroxyquinoxaline, 748.
 Diphenyltriamidobenzene, condensation of, with benzoin, 748.
 Diphenyltriketone, 818.
 — hydrate, 319.

- Diphenyltriketoneanilide, 319.
 Diphenyltriketonedianilide, 319.
 Diphenyltrinitrosopropane, 319.
 Diphthalylamidoethyl sulphide, 815.
 — sulphoxide, 816.
 Diphthalylimidoethyl bisulphide, 817.
 Diphthalylimidopropyl bisulphide, β -, 1473.
 Dipiperidyl, $\alpha\beta$ -, 583.
 — γ -, and its derivatives, 1094.
 Dipiperidylbromisatin, 1491.
 Dipiperidylisatin, 928.
 Dipiperonylacryl ketone, 704.
 — — dibromo-, 1475.
 — — dinitro-, 705.
 Dipropargyl, isomeric change in, 1332.
 Dipropyl α -sulphaminephthalate, 1063.
 Dipropylacetylene dibutyrate, 891.
 Dipropylamine, molecular refraction and dispersion of, *TRANS.*, 296.
 Dipropylbenzene, para-, 1022.
 — dinitrodibromopara-, 1022.
 Dipropylbenzenes, synthesis of, 685.
 Dipropylbenzenesulphonic acid, meta-, 685.
 — acids, para-, 1022.
 Dipropylene, β -, 282.
 Dipropylethylamine, 1118.
 Dipropylglycollic acid, 891.
 Dipropylmethylethylamine, 1118.
 Dipropylnitramine, 168.
 Dipropylpimelic acid, *TRANS.*, 838.
 Diprydil, γ -, 1093.
 Dipyropentylene, 1085.
 Diquinolyl, 2' : 3', 83.
 Diquinyl ketone, 1106.
 Diresorcinol, detection of, in synthetically prepared phloroglucinol, 125.
 Diresorcinyll tetrethyl ether, 76.
 Disalicylbenzoin, 708.
 Disazobenzene α -chlorophenylhydrazine, tetranitronitroso-, 907.
 Disazo-compounds of α -naphthol, molecular change in the formation of, 1075.
 Disodammonium chloride, 642.
 Disodium erythroxide, 999.
 Dispersion and chemical constitution, relation between, 774.
 — in certain metals, 373.
 — molecular, of various substances in solution, *TRANS.*, 589.
 — of various carbon compounds, 774, *TRANS.*, 290.
 — rotatory, of tartrates, 1145.
 Dispersive power of organic compounds, 138, 774, *TRANS.*, 290.
 Dissociating gases, function of, 870.
 Dissociation, continued, 881.
 — electrolytic, and the molecular theory, 390.
 — — formulæ for, 1309.
 Dissociation, electrolytic, hypothesis of, 521.

— acetyltrimethylenecarboxylate, action of isoamyl iodide and sodium ethoxide on, TRANS., 892.

— — molecular refraction and dispersion of, TRANS., 295.

— aconitate, action of ethyl sodiomalonate on, 546.

— acrylate, action of ethyl alcohol on, TRANS., 475.

— alcohol, action of iodine on, 656.

— — solutions, specific heats of, 1406.

— allyl ether, action of hydrogen chloride and bromide on, 164.

— allylacetate, action of alcoholic sodium ethoxide on, TRANS., 482.

— allylmethylbenzoylacetate, TRANS., 999.

— amilobenzoate (ortho-), action of ammonia on derivatives of, 912.

— amidocrotonate, action of heat on, TRANS., 172.

— amidoethylenedicarboxylate, TRANS., 747.

— — action of baryta on, 740.

— α -amido- α -ethylideneglutarate, lactam of, 1187.

— α -amidoethylidenesuccinate and its derivatives, 544.

— β -amidoglutaconate, 423.

— amidomicrobenzoate, 912.

— μ -amidothiazoledicarboxylate, 224.

— μ -amidothiazylacetate, 743.

— amidotolylcarbamates, isomeric, 702.

— angelate, action of alcoholic sodium ethoxide on, TRANS., 482.

— α -anilido- α -ethylideneglutarate, lactam of, 1187.

— benzalmalonate, action of ethyl sodacetacetate on, 712.

— benzamidoxalacetate, 922.

— benzamidylcarbamate, 59.

— benzenebisazo- $\Delta^{1,4}$ -dihydroterephthalate, 1487.

— benzenebisazo- $\Delta^{2,5}$ -dihydroterephthalate, 1487.

— benzenebisazoterephthalate, 1487.

Ethyl benzenedihydrazo- $\Delta^{2,5}$ -dihydroterephthalate (para-), 1486.

— benzoylacetate, condensation of, with furfuraldehyde, TRANS., 1011.

— 3-benzoyldihydrocollidinecarboxylate, 1091.

— benzoylsodacetate and chloracetone, reaction between, TRANS., 191.

— benzylbenzoylacetate, TRANS., 1006.

— benzylidicarboxylglutaconate, 179.

— — action of ammonia on, TRANS., 748.

— bromethylamido- α -crotonate, 817.

— bromide, molecular refraction and dispersion of, TRANS., 295.

— bromocaprylate, 1190.

— bromomethylacetacetate, 223.

— bromo- β -naphthoate, 934.

— bromostearate, 1190.

— butanepentacarboxylate, 421.

— carbamate, action of parachlorophenylhydrazine on, TRANS., 211.

— carboxylglutarate, 547.

— chloracetacetate, action of sodium phenylmercaptide on, 712.

— chloralimidocarboxylate, 1003.

— chlorethylmaphthylcarbamates, 1373.

— chlorocarbonate, action of, on sodium formate, acetate, &c., 288.

— chlorofumarate, molecular refraction and dispersion of, TRANS., 295.

— chloromalonate, action of phenylhydrazine on, 1068.

— α -chloromethylacetacetate, 223.

— chlorophenylhydrazinepyruvate (ortho-), TRANS., 211.

— chrysylcarbamate, 730.

— cinnamate, additive compound of, with ethyl sodacetacetate, 914.

— citradibromopyrrolate, 1185.

— cresyl ether, brom-, 552.

— — imido-, 552.

— crotonate, action of ethyl alcohol on, TRANS., 478.

— cuproacetonedicarboxylate, 673.

— cuprobenzoylacetate, 459.

— cyanide, dimolecular, 888.

— diazobenzoate, 55.

— dibenzoylacetate, action of phenylhydrazine on, TRANS., 1005.

— — preparation and properties of, TRANS., 1000.

— dibenzoylmethylacetate, TRANS., 1005.

— $\alpha\alpha'$ -dibenzylacetonedicarboxylate, 674.

— dibenzylpentanetetra-carboxylate, TRANS., 843.

— dibromhydromuconate, TRANS., 752.

— $\alpha\beta$ -dibromobutyrate, 1184.

- Ethyl dibromopentametetracarboxylate, TRANS., 827.
- dibromoquinoneterephthalate, 456
- dibromosuccinate, action of ethylenediamine on, 1004.
- — action of zinc on, 1184, 1338.
- dicarboxylglutamate, action of ammonia on, TRANS., 745.
- — alkyl substitution products of, 178.
- dichloracetate, action of, on the sodium derivative of ethyl malonate, PROC., 1891, 41.
- dichlorisopropylcarbamate, 1374.
- dichlorisopropylchlorocarbamate, 1374.
- dichlorisopropyl-naphthylcarbamates, 1374.

 — — fermentation of starch by, 660
 — diastatic, in urine, 760
 — glycolytic, of the blood, isolation of, 755
 — of nitrification, 352
 — oxalic, 857
 — soluble, of urea, 100
 Fermentation, alcoholic, by "champignon du muguet," 854
 — new, of starch, 1284
 — of bread, 1532
 — of calcium glycolate by the *Bacillus ethaceticus*, TRANS, 81
 — of cherry and currant juice, 1589
 — production of the higher alcohols in, 411
 Fermentations, acetic and lactic, influence of artificial gastric juice on, 488
 — induced by the *Pneumococcus* of Friedlander, TRANS, 253.

Fermentations, lactic and butyric, action of mineral acids on, 488.
 Ferments, digestive, excretion of, 483.
 ——— influence of temperature on, 1271.
 ——— value of nitrates and ammonium salts as food for, 1135.
 Ferric chloride, molecular refraction and dispersion of, in solution, TRANS., 595.
 ——— reduction of, by light, 965.
 ——— dextrosate, TRANS., 325.
 ——— hypophosphite, assay of, 1290.
 ——— oxide, estimation of, in phosphates, 501, 963.
 ——— estimation of, in phosphatic manures, 245.
 ——— separation of, from alumina, 1293.
 ——— salts and thiocyanates, reaction between, 1150.
 ——— selenites, 262.
 ——— sulphates from Chili, 274.
 Ferrocyanides, reactions of, 410.
 Ferrocyanides, estimation of, 247.
 ——— estimation of, in gas-refuse, 367.
 Ferro-goslarite, 992.
 Ferromanganese, crystalline, 646.
 Ferronitrate, 649.
 ——— from Chili, 274.
 Ferropentacarbonyl, TRANS., 1091.
 Fever, elimination of urea in, 1530.
 ——— increased output of nitrogen in, 600.
 Fibre, crude, estimation of, 865.
 ——— vegetable, action of nitric and sulphuric acids on, 814.
 Fibres, vegetable, action of nitric acid on, 1001.
 Fibrinogens, tissue, 1524.
 Fig wine, 1135.
 Filters, dried, weighing of, 613.
 Filtration, rapid, of organic liquids, use of liquefied carbonic anhydride for, 854.
 Fisetin, 1386.
 Fisetol, 1387.
 ——— dimethyl ether, 1387.
 ——— ethyl ether, 1387.
 ——— ethyl ether, 1386.
 ——— triethyl ether, 1387.
 Flame, nature of, 1309.
 Flavopurpurin, conversion of anthraquinone-*a*-disulphonic acid into, 934.
 Flinkite from Harstigen Mine, Sweden, 20.
 Flour, action of sulphurous anhydride on, 95.
 ——— bacteria from, 1532.
 Fluorene hydrides, 814.
 Fluorides, action of, on yeast, 1532.
 Fluorine, atomic dispersion of, 774.

Fluorine, atomic weight of, 15.
 ——— estimation of, 615.
 ——— free, probable occurrence of, in the fluorspar of Quincí, 149.
 Fluorspar from Quincí, 148.
 Fodder, estimation of free fatty acids in, 770.
 ——— influence of heat on the digestibility of, 752.
 Fodders, analysis of, with special reference to the proteids, 858.
 Food free from nitrogen, influence of proteids on the digestion of, 344.
 ——— rations of grown animals, effect of increasing the proteids in, 753.
 Foods, peptonised, 953.
 Formaldehyde, action of, on phenols, 1199.
 ——— formation of starch from, 1539.
 Formaldehydes, thio-, polymeric, 1011.
 Formates, action of ethyl chlorocarbonate on, 288.
 Formic acid, estimation of, in presence of acetic and butyric acids, 248.
 Formoparatoluidide, 1202.
 Formoxime and its polymerides, 663.
 Formylacetic acid, oximido-, 1458.
 Formylcamphor, 574.
 Formylcarbamide, thermochemistry of, 1448.
 Formylchloralimide, 1003.
 Formyldiorthamidobenzamide, 909.
 Formylfenchylamine, 1087.
 Formylorthamidobenzomethamide, 909.
 Formylorthomethamidobenzamide, 910.
 Formylparachlorophenylhydrazine, TRANS., 213.
 Formylparamidobenzoic acid, 304.
 Fowlerite from New Jersey, 530.
 Freezing point, adhesion at the, 969.
 ——— and electrical conductivity, 971.
 ——— determinations, apparatus for, 784.
 ——— of gold containing aluminium or silver, 1161.
 ——— of solutions, abnormal depression of, 1411.
 ——— of triple alloys of gold, cadmium, and tin, TRANS., 936.
 ——— points, determination of, with the platinum thermometer, 251.
 ——— of dilute aqueous solutions of electrolytes and non-electrolytes, 971.
 ——— of dilute solutions, 1148.
 Fructose, d-, and l-, configuration of, 1176, 1445.
 Fulminic acid, constitution of, 282, 446.
 Fumaramic acid, 177.
 Fumarilic acid, 177.
 ——— chloride, 176.

Fumaric acid, conversion of maleic acid into, 1338.
 ——— chloride, chloro-, molecular refraction and dispersion of, TRANS., 295.
 ——— diamilide, 1220.
 ——— α -dinaphthalide, 1220.
 Fungi, sugars present in, 954.
 Fungus symbiosis of the Leguminosae, 353.
 Furazancarboxylic acid, 827, 896, 1184.
 Furazanpropionic acid, 418.
 ——— amidoxime, 419.
 ——— anhydride, 418.
 Furfuracrylic acid, preparation of ethereal salts of, 427.
 Furfuraldehyde, action of, on animals, 1893.
 ——— formation, detection and significance of, 867.
 Furfurallevulinic acid, 1456.
 Furfurisophthalic acid, 1065.
 Furfurphenyldihydro- β -naphthathiazine, 841.
 Furfurylamine, action of methyl iodide on, 294.
 Fusel oil, estimation of, in spirits, 622, 1556.

G.

Gadolinite, 1168.
 Gadolinite-earths, separation of, 1426.
 Gadolinium chloride, spark spectrum of, 2.
 ———, Marignac's, 17.
 Gahnite from Delaware Co., Pennsylvania, 1168.
 Galactangeddic acid, TRANS., 1057.
 Galacto-arabane, 1179.
 Galactonic acid, rotatory power of, 43.
 Galactose, estimation of, 1143.
 Galactosoxime, 665.
 Galic acid, 713.
 Gallic acid, 70.
 ——— action of formaldehyde on, 1199.
 ——— conversion of, into beuzoic acid, 1481.
 ——— molecular weight of, 145.
 ——— oxidation of, 713.
 Gallisin, preparation and properties of, 586.
 Galvanic cells of certain metals, platinum, and nitric acid, variations of E.M.F. in, 514.
 ——— relation between electrical and chemical energy in, 518.
 ——— elements, electromotive force of, 514.
 Garnet from Canada, 647.

Garnet from Kedabek, in Caucasia, 1169.
 Garnet-group, minerals of the, 24.
 Gas, coal-, estimation of cyanogen in 367.
 ——— compressed, terpene in the oil from, 1085.
 ——— determination of the absolute density of, 379.
 ——— determination of the weight of, from the volume, TRANS., 894.
 ——— illuminating, detection of sulphur not combined with hydrogen in, 862.
 Gas-battery, 374.
 Gaseous mixtures, influence of temperature on the limits of the explosion of, 975.
 Gases, apparatus for the analysis of, 240.
 ——— chamber exit, testing, 407.
 ——— compressibility of, 378.
 ——— dissociating, law of, 780.
 ——— dissociation of, by the silent discharge, 113.
 ——— effusion of, 381.
 ——— kinetic theory of, and osmotic pressure, 638.
 ——— osmotic pressure from the standpoint of, 389.
 ——— measurement of, 1135.
 ——— mixed, slow combustion of, 1153.
 ——— pressure of compressed, 520.
 ——— pyrites burner, testing, 496.
 ——— rapid preparation of, 14.
 ——— refraction and constitution of, 629.
 ——— respiratory exchange of, 1270.
 ——— solubility of, in water, 884.
 Gasholder, universal, 1414.
 Gas-refuse, estimation of ferrocyanides in, 867.
 Gastric juice, artificial, influence of, on the acetic and lactic fermentations, 488.
 ——— detection of hydrochloric acid in, 767.
 ——— estimation of free hydrochloric acid in, 593, 613, 767.
 Gas-works, examination of water for contamination by, 117.
 Gedda gum, proteid from, TRANS., 1061.
 ——— gums, TRANS., 1029.
 Geddic acids, TRANS., 1029.
 Geddinosis acid, TRANS., 1041.
 Geddinosis acid, β -, TRANS., 1054.
 Gelatin and metaphosphoric acid, compounds of, 477.
 ——— digestion of, 949.
 Gelatin-peptone, 950.
 Gentianin, 1244, 1386.
 Gentisin, 1244, 1386.

- Geranialdehyde, 323, 539.
 — tetrabromide, 539.
 Geranic acid, 323.
 Geraniol, oxidation of, 30.
 Geranium essence, Turkish, detection of, in oil of roses, 1555.
 — oil, Indian, 30, 287, 323.
 Germanium oxide, action of magnesium on, 802.
 Germinating barley, influence of temperature on, TRANS., 664.
 Germination, change in the nitrogenous substances of barley during, 489.
 — conversion of starch during, 357.
 — mode of solution of reserve cellulose during, 356.
 — normal, behaviour of fatty substances and the rôle of the lecithins during, 489.
 Gerontine, 538.
 Gibbsite, so-called, from Pennsylvania, 275.
 Glass, solvent action of hot water on, 634.
Gleditsia triacanthos, nitrogen assimilation of, 1533, 1536.
 Globulin, a bactericidal, 352.
 — which kills bacteria, 352.
 Glucobiose, synthesis of a new, 412.
 Gluconic acid, oxidation of, with Fehling's solution, 426.
 — — rotatory power of, 43.
 Glucose, estimation of, 1143.
 — fermentation of, with Friedlander's *Pneumococcus*, TRANS., 254.
 — formation of, in the organism, 1125, 1392.
 — in organs with impeded circulation and in hydrocyanic acid poisoning, 1126.
 Glucose, d-, configuration of, 1176, 1445.
 Glucose, l-, configuration of, 1176, 1445.
 Glucosoxime, 513.
 Glue, products of the artificial digestion of, 232.
 Glutamic acid, condensation of, with benzenesulphonic chloride, 202.
 — — inactive, 420.
 Glutaramide, 62.
 Glutaramidine salts, 62.
 Glutaramidyl acetate, 62.
 — ethyl ether hydrochloride, 61.
 — isobutyl ether hydrochloride, 62.
 — methyl ether hydrochloride, 61.
 Glutaric acid, action of heat on, 1011.
 — — amido-, 420.
 — — bromination of, 1191.
 — — decomposition of, by sunlight, in presence of a uranium salt, 1004.
 Glutaric acid, dibromo-, 1191.
 — — α -nitroso-, 419.
 — — preparation of, TRANS., 993.
 — acids, α -dialkyl-, a new synthesis of, 178.
 Gluten, action of sulphurous and other acids on, 95.
 Gluten-casein, digestion products of, 342.
 Glutinopeptone, 233.
 Glucose, 232.
 Glyceric acid, an optically active, TRANS., 96.
 — — optically active, crystalline form of the calcium salt of, TRANS., 233.
 Glycerol, action of, on albumin, 589.
 — bases formed by the action of ammonium salts on, 581.
 — influence of, on gaseous metabolism, 345.
 — molecular refraction and dispersion of, TRANS., 295.
 — volumetric estimation of, in wine, 369.
 Glyceryl pyruvate, 1018.
 Glycocine, amido-, 56.
 — and its anhydride, molecular weight of, 38.
 — preparation of, 38.
 Glycogen, deposits of, in the tissues, 1271.
 — formation of, in the liver, 1526.
 — of the liver, influence of alkalis on, 758.
 Glycol chlorhydrin, action of benzylamine on, 1351.
 — chlorhydrins, action of carbonic chloride on, 1373.
 Glycolysis in the blood, 1528.
 Glycolytic ferment in the blood, isolation of, 755.
 Glycosuria, chemical detection of, 300.
 Glycuronic acid, formation of, during inanition, 1529.
 — — reduction of, by sodium amalgam, 294.
 — — synthesis of, 677.
 Glyoxal, condensation products of, with some mercaptans, 186.
 Glyoxime peroxide, 232.
 Glyoximes, action of nitric peroxide on, 315.
 Glyoxylpropionic acid and its derivatives, 416.
 Goethite from Nova Scotia, 647.
 Gold, action of nitrosyl chloride on, TRANS., 662.
 — cadmium and tin, freezing point of triple alloys of, TRANS., 936.
 — containing aluminium or silver, freezing point of, 1161.

Gold containing aluminium, cooling of, 1161.
 — electrolytic estimation and separation of, 1140, 1141, 1296, 1396.
 — electrolytic estimation of, 1140, 1296.
 — electrolytic separation of, from cobalt, 1141, 1396.
 — electrolytic separation of, from cobalt, copper, nickel, palladium, and platinum, 1396.
 — electrolytic separation of, from zinc, 1140.
 — in turquoise, from New Mexico, 155.
 — removal of, from suspension and solution, by fungoid growths, 401.
 — sulphides, colloidal, 1162.
Gonolobus condurango, constituents of the bark of, 1387.
 Gordaite, 649.
 Grape sugar and its isomerides, configuration of, 1173, 1444.
 — influence of inactive substances on the rotatory power of, 1178.
 Graphite, formation of, by contact metamorphosis, 989.
 Grass oils, Indian, 283.
 Gravivolumeter, *TRANS.*, 894.
 Grense, estimation of, 1144.
 Greenockite, synthesis of, 990.
 Griphite from Dakota, 1328.
 Grossularite, pink, from Mexico, 993.
 Guaiacol, physiological action of, 99.
 Guanaajualite, 1328.
 Guanamines, 416.
 Guanidine, 1180.
 — condensation of, with ethereal salts of ketonic acids, 1007.
 — picrate, 1180.
 Gulonic acid, d.-, preparation of, 678.
 — l.-, 667.
 Gulonolactone, i.-, 668.
 Guloose, d.-, 678.
 — configuration of, 1176, 1445.
 Guloose, l.-, 667.
 — configuration of, 1176, 1445.
 Gum arabic, 866.
 — adulteration of, with gum senegal, 866.
 — from the sugar-beet, 284.
 — senegal, 866.
 — wood-, 659.
 Gums, gceda, *TRANS.*, 1029.
 — of the arabin group, *TRANS.*, 1029.
 Guvaccine, 1520.
Gymnema latifolium, amygdalin in the leaves of, 338.

H.

Hæmatin, vegetable, 751, 845.
 Hæmatoporphyrin in urine, 601, 1130, 1279.
 Hæmatoporphyrinuria, 601, 1130, 1279.
 Hæmocyanin, preservation of, 591.
 Hæmoglobin, 845.
 — compounds of, with carbonic anhydride, 343.
 — crystallisation of, 343.
 — cutaneous pigment as an antecedent of, 480.
 — in blood, increase of, at great altitudes, 754.
 — transformation of, in the bile, 432.
 Halogens, action of, on aromatic compounds in presence of light, 893.
 — and metals, velocity of reaction between, 1119.
 — displacement of, by the amido-group, 36.
 — surface tension of the, 257.
 Haloid compounds, magnetic rotation of, *Proc.*, 1890, 142.
 Halotrichite from Colorado, 993.
 Hamlinite, 20.
 Hardness of natural waters, estimation of, 116.
 — of water, estimation of, 1554.
 Hay, digestibility of, 595.
 Heart, action of nicotine on, 96.
 Heat changes in the hydrogenation of closed chains, 377.
 — endothermic and exothermic reaction of organic bases, 377.
 — influence of, on the digestibility of fodder, 752.
 — of combustion and constitution of organic compounds, 632.
 — and structural formulæ of alkylene oxides, acetaldehyde and its polymerides, trimethylene, and benzene, 633.
 — of coal, use of the calorimetric bomb in determining, 520.
 — of hydromellitic and hydroterephthalic acids, 1147.
 — of organic compounds, 251.
 — of solid bibasic acids, relations of, to those of the gaseous hydrocarbons, 252.
 — of dissolution of carbon compounds in various alcohols, 1313.
 — of formation of bibasic erythroxydes, 1312.
 — of neutralisation, 1406.
 — phosphorescence of minerals under the influence of, 776.
 — specific of mercury, 632.
 Heat. See also Thermochemistry.

- Heats of combustion and formation of
fats and fatty acids, 11.
— of organic chlorine com-
pounds, 1811.
— of terephthalic acid,
and its hydrogenated derivatives,
376.
— specific, of some solutions, 1406.
Heintzite, 528.
Heliophyllite from Harstigen Mine,
Sweden, 20.
Helx pomatia, the so-called liver of, 235.
Hemato-alkalimetry, new method of,
348.
Hemicelluloses, 1179.
Hemimellibenzaldehyde, 1353.
Hemimellibenzyl alcohol, 1352.
Hemimellibenzylamine, 1352.
Heptanaphtheneamine, 1452.
Heptanaphthenecarboxylic acid and its
derivatives, 1452.
Heptane, molecular refraction and dis-
persion of, TRANS., 295.
Heptarabinanpentagalactangeddic acid,
TRANS., 1074.
Heptarabinantrigalactangeddic acid,
TRANS., 1071.
Heptarabinantrigalactangeddic acid,
TRANS., 1065.
Hernandia sonora and *H. ovigera*,
alkaloid from, 388.
Hexadecylmalonamic acid, 1451.
Hexadecylmalonic acid, 1451.
Hexahydrobenzoic acid, and its deriva-
tives, 1481.
Hexahydronicotinic acid hydrochloride,
735.
Hexahydropseudocumene, 185.
Hexahydroterephthalic acid, cis-, heats
of combustion and formation of, 376.
— fumaroid, heats of combus-
tion and formation of, 376.
Hexahydroxyanthraquinone, 935.
Hexamethoxybenzile, 1219.
Hexamethoxybenzilic acid, 1219.
Hexamethoxydeoxybenzoin, 1219.
Hexamethoxyhydrobenzoin, 1219.
Hexamethylenamine, additive products
of, 663.
— behaviour of, with various re-
agents, 1179.
— tetrasilver bromide, 818.
Hexamethylene-derivatives, synthesis of,
TRANS., 798.
Hexamethylenedicarboxylic acids, new
synthesis of, TRANS., 990.
— anhydride Γ^{100} , TRANS., 812.
Hexamethylenemetadicarboxylic acid,
 Γ^{100} , TRANS., 808.
— Γ^{100} , TRANS., 814.
— acids, conversion of one into the
other form of, TRANS., 813, 816, 817.
Hexamethylenetetracarboxylic acid
[1:1:3:3], TRANS., 804.
— formation of, TRANS., 994.
Hexamethyltriamidophenylditolyl-
methane, 728.
Hexamethyltriamidotriphenylsulphine
hydroxide, 715.
— salts, 714.
Hexamethyltriamidotritolylmethane,
729.
Hexamethyltriamidotrixylylmethane,
729.
Hexane, normal, heats of combustion
and formation of, 376.
Hexarabinanpentagalactangeddic acid,
TRANS., 1074.
Hexarabinantrigalactangeddic acid,
TRANS., 1065.
Hexyl sulphide, occurrence of, in Ohio
petroleum, 1173.
Hexylene dibromide obtained from
diallyl, 160.
Hexylparatolyldihydrotolutriazine, 842.
Hexylphenyldihydro- β -naphthatriazine,
841.
Hintzeite, 528.
Hippuro-phosphates, 98.
Hippurylbenzylhydrazine, 57.
Hippurylhydrazine, 56.
— nitroso-, 57.
Homarecoline, 95.
Homilite, 1168.
Homobenzenylamidine hydrochloride,
para-, 560.
— parahomobenzenylazosulphime-
carbohydrosulphide, para-, 560.
Homobenzenylamidossulphime para-
homobenzenylsulphimeditiocarb-
amate, para-, 560.
Homobenzenylamidoxine, para-, action
of carbon bisulphide on, 559.
Homobenzenylazosulphimecarbabisulph-
ide, para-, 560.
Homobenzenylazosulphimecarbohydro-
sulphide, para-, 560.
Homobenzhydrylamine, meta-, 1480.
— ortho-, 1480.
— para-, 1479.
Homobenzhydrylcarbamide, 1480.
Homobenzhydrylphenylcarbamide,
para-, 1480.
Homobenzhydrylthiocarbamide, para-,
1480.
Homochelidonine, 844.
— α -, 229.
— β -, 229.
Homocumic acid and its derivatives,
1057.
Homogentisic acid, 1129.
Homologous compounds, vapour pres-
sure of, 969.
Homology, alicyclic, 1097.

- Homopiperidinic acid, derivatives of, 466, 1246.
- Homoterephthalic acid, and its derivatives, 1057.
- Honey, pine tree, 412.
- Honey-dew, pine tree, 412.
- Hops, estimation of tannin in, 870.
- Hornblende, artificial, 1430.
- from the Lizard, 276.
- Hornblendes, basaltic, 649.
- Horse, sweat of the, 349.
- Humic acid, 1089.
- from sugar, thermochemistry of, 1456.
- anhydride, 1089.
- compounds, 1089.
- Humus as manure, 859.
- estimation of, in soil, 627.
- Hunteria corymbosa*, alkaloid from, 336.
- Hyalite, artificial production of, at the ordinary temperature, 991.
- Hydantoic acid, thio-, 180.
- Hydantoïn, thio-, 179.
- Hydatid cysts, liquids from, 97.
- Hydrocarpus*, hydrocyanic acid in, 338.
- Hydracrylic acid, 170.
- Hydrastine, 1518.
- alkyl derivatives of, 92, 93.
- allyl iodide, 93.
- Hydrastophthalimidine, 94.
- Hydratropaldehyde, 898.
- Hydrazine, 263.
- dihydriodide, 264.
- dihydrobromide, 264.
- dihydrofluoride, 264.
- hydrate, 263.
- action of, on benzophenone, 1358.
- — on isatin and phenols, 1360.
- — on ketones and ortho-diketones, 1355.
- α -hydrazopropionate, 39.
- monohydriodide, 264.
- monohydrobromide, 264.
- physiological action of, 239.
- poisonous action of, 239.
- sulphate, 263.
- Hydrazineacetic acid, 56.
- Hydrazineamidodiphenyldisulphonic acid, 930.
- Hydrazinehippuric acid, nitroso-, 57.
- Hydrazines, physiological action of, 1280.
- Hydrazisatin, 1360.
- Hydrazobenzene, pariodo-, 211.
- Hydrindene, 206.
- Hydriodic acid, action of, on substances containing sulphur, 1296.
- and bromic acids, influence of mineral acids on the velocity of reaction between, 144.
- Hydriodic acid, molecular refraction and dispersion of, in solution, TRANS., 593.
- Hydriodocinchonine, 1517.
- Hydrobenzoïn dibenzoate, 931.
- preparation of, 1402.
- Hydrobenzoïns and their anhydrides, 1069.
- oxidation of, 1069.
- Hydroberberine, 332.
- Hydrobromanhydroecgonine hydrobromide, 94.
- Hydrobromic acid, molecular refraction and dispersion of, in solution, TRANS., 593.
- preparation of, 976, 1320.
- Hydrocarbons, aromatic, heat of combustion and constitution of, 632.
- ring, and nucleus structure of, 1343.
- substitution in, 44.
- substitution of halogens in, 1020.
- closed-chain, heats of combustion and chemical constitution of, 632.
- fatty, velocity of the halogenisation of, 145.
- gaseous, relation of the heats of combustion of solid bibasic acids to those of, 252.
- melting points of binary mixtures of, 1495.
- spectra of, 773.
- synthesis of, 685.
- unsaturated, and phenols, condensation of, 203, 571.
- isomeric change in, 1330.
- volatile, volumetric estimation of, 1141.
- Hydrochloric acid, aqueous coefficients of volatility for, 798.
- estimation of, in gastric juice, 593.
- free, estimation of, in gastric juice, 593, 613, 767.
- estimation of, in presence of acid phosphates, 1288.
- estimation of, in stannous chloride solutions, 241.
- molecular refraction and dispersion of, in solution, TRANS., 593.

- Hydrochlorobutallylmethylcarbinamine, 1507.
- Hydrochlorobutallylmethylcarbindimethylamine, 1508.
- Hydrochloropentallylcarbindimethylamine salts, 1508.
- Hydrocinnamanilide, PROC., 1891, 71.

- Hydrocinnamic chloride, *Proc.*, 1891, 71.
 ——— action of aluminium chloride, on, *Proc.*, 1891, 71.
 Hydrocinnamide, *Proc.*, 1891, 71.
 Hydrocotarnine, physiological activity of, 762.
 Hydrocotoln, a constituent of coto-bark, 578.
 Hydrocyanic acid, distribution of, in the vegetable kingdom, 338.
 ——— poisoning by, applied to the surface of the eye, 99.
 Hydrodiffusion, 333.
 Hydrogen and air, compressibility of mixtures of, 634.
 ——— and oxygen, admixed, slow combustion of, 1153.
 ——— arsenide and silver nitrate, reaction between, 1154.
 ——— compressibility of, 378.
 ——— density of, 1416.
 ——— fluoride, action of, on yeast, 1532.
 ——— nitride, 56, 524.
 ——— nitride, N_2H_4 , preparation of, 262.
 ——— passivity of, 392.
 ——— peroxide, bleaching of cotton by, 1447.
 ——— detection of minute quantities of, 360.
 ——— influence of temperature on the formation of, from ether, *TRANS.*, 56.
 ——— test for, 1549.
 ——— phosphide, action of phosphorous chloride on, 398.
 ——— preparation of, 397.
 ——— solubility of, in alcohol, 15.
 ——— solubility of, in water, 15, 384.
 ——— spectrum of, 1.
 ——— sulphide and sulphurous anhydride, estimation of, in admixture, 498.
 ——— biogenesis of, 102.
 ——— dry, action of, on metals, 990.
 Hydrogenation of closed chains, 376, 1146.
 Hydrohydrastinine methochloride, 1519.
 ——— preparation of, 1518.
 Hydro- α -methylindole, action of methyl iodide on, 311.
 Hydromethylketole, reactions of, 1007.
 Hydroplumbite, 275.
 Hydroptyalin, 483.
 Hydroquercic acid, 1061.
 Hydroquercic acid, 1062.
 Hydroquinaldine, colouring matters from, 1102.
 Hydrotaraphthalic acids, heats of combustion of, 1147.
 Hydrotiazole derivatives, attempts to prepare, 744.
 Hydroxides of the alkali metals, magnetic rotation of, *Proc.*, 1890, 143.
 Hydroxy-acids, action of alkali hydro-sulphides on, 46.
 ——— α -, action of phenylhydrazine on, 438.
 ——— decomposition products of, 1457.
 ——— velocity of lactone-formation in the case of, 822.
 Hydroxyacridine, 1233.
 Hydroxyacridylbenzoic acid, 1234.
 Hydroxylizarin-blue, 1383.
 Hydroxylizarin-blue-sulphonic acid, 1383.
 Hydroxyamidobenzoic acid, meta-, 1037.
 Hydroxyamidodiphenyldisulphonic acid, 929.
 Hydroxazobenzene, action of phosphoric chloride on, 801.
 Hydroxyazo-compounds, 1209.
 ——— para-, reduction of, 1210.
 Hydroxyazo-dyes, ortho-, 1038, 1473.
 Hydroxazotoluquinoline, 328.
 Hydroxybenzaldehyde, meta-, derivatives of, 699.
 Hydroxybenzenylamidoxime, meta-, 699.
 ——— para-, 700.
 Hydroxybenzenylazoximebenzenyl, para-, 700.
 Hydroxybenzenylazoximepropenyl- ω -carboxylic acid, meta-, 699.
 ——— para-, 700.
 Hydroxybenzenylazoximethenyl, meta-, 700.
 ——— para-, 700.
 Hydroxybenzenylphenylhydrazone, meta-, 699.
 Hydroxybenzoic acid, dichloropara-, 710.
 ——— iodomet-, 1037.
 ——— nitro-, 917.
 ——— tetrachloromet-, 709.
 ——— trichloromet-, 709.
 ——— acids, action of chlorine on, 708.
 ——— action of diazo-compounds with, 1473.
 ——— azo-dyes from, 1038.
 ——— nitration of, with nitrous acid, 307.
 Hydroxybenzylamine, ortho-, 50.
 Hydroxybenzyltrimethylhydroxypyrimidine, 63.
 Hydroxybenzylethylmethylhydroxypyrimidine, 63.
 Hydroxybenzylmethylhydroxypyrimidine, 63.
 Hydroxybenzylphenylhydroxypyrimidine, 63.
 Hydroxybenzyltrimethylenecarboxylic acid, *TRANS.*, 884.

Hydroxydiphenyl, para-, synthesis of, from aniline, 437.
 Hydroxydiphenylethane, 208.
 Hydroxydiphenylpropionic acid, 1484.
 Hydroxyethylamine, preparation of, 1373.
 Hydroxyethylnaphthylamines, 1374.
 Hydroxyethyltrimethylenecarboxylic acid, TRANS., 870.
 Hydroxyglutaric acid, γ -, 421.
 Hydroxyhydromucic acid, bromo-, lactone of, TRANS., 758.
 Hydroxyimidomethyluracil, 1007.
 Hydroxyhydrazole, 312.
 Hydroxyisoxazoledicarboxylic acid, 738.
 Hydroxyketone dyes, 706.
 Hydroxyketones from fatty acids and phenols, 447.
 Hydroxylamine, action of, on animals, 1393.
 — constitution of the amido-derivatives of, 697.
 — hydrochloride, estimation of hydrogen chloride in solutions of, 107.
 — stereochemical isomerism of derivatives of, 1032.
 — thiocarbimide, 1222.
 Hydroxylapachone, 1210.
 Hydroxylepidine-1-carboxylic acid, α -, 737.
 Hydroxylevulinic acid, 1185.
 — α -, 1187.
 Hydroxyl group, reagent for, 49.
 Hydroxymetatoluquinoline, nitro-ortho-, 326.
 — ortho-, 326.
 Hydroxymetaxyloquinoline, 328.
 Hydroxymethylacridine, 1233.
 Hydroxymethylhydrodrastinine methiodide, bromo-, 1520.
 Hydroxymethylmalonic acid, 175.
 Hydroxymethylquinoline, ortho-, 326.
 Hydroxymethylxanthone, β -, 1060.
 — bisulphide, β -, 321.
 — sulphide, β -, 320.
 Hydroxypalmitic acid, α -, 820.
 Hydroxyparatoluquinoline, 326.
 — nitroso-, 326.
 — orthonitro-, 326.
 Hydroxyparazobenzenesulphonic acid, salts of, 1037.
 Hydroxyphenindulone, chlor-, 747.
 Hydroxyphenylacridine, 1234.
 Hydroxyphenylallylthiocarbamide, ortho-, 52.
 Hydroxyphenylimidomethylene ethylene bisulphide, 895.
 Hydroxyphenylindazole, 2'-para-, 724.
 Hydroxypropamidine salts, 63.
 Hydroxypropionitrile, imido-ethers of, 62.

Hydroxy- β -propylidinebutyramide, α -, 38.
 Hydroxypyruvic acid, 542.
 Hydroxyquinoline, action of chlorine on, 1249.
 — benzylchloride, para-, 1253.
 — benzylhydroxide, para-, 1253.
 — chloro-, 1249.
 — dichloro-, 1249.
 — dinitroortho-, 579.
 — ethobromide, para-, 1253.
 — ethohydroxide, para-, 1253.
 — methochloride, para-, 1252.
 — methohydroxide, para-, 1252.
 — methosulphate, para-, 1252.
 — 1 : 4-nitroortho-, 579.
 — trichloro-, 1250.
 Hydroxyquinolinecarboxylic acid, 1342.
 Hydroxyquinolinemethylbetaine, para-, 1252.
 Hydroxyquinolinequinone, chlor-, 1251.
 Hydroxyquinolinequinoneamide, chlor-, 1251.
 Hydroxyquinone, parachlor-, 456.
 Hydroxystearic acid, α -, 1336.
 Hydroxytetric acids, real nature of, 1188.
 Hydroxythymophenindulone, 747.
 Hydroxythymoquinone derivatives, constitution of, 297.
 Hydroxy-3 : 4 : 1'-tribromoquinoline, 1-, 83.
 Hydroxy- α -truxillic acid, β -, 1496.
 Hydroxyvaleric acid, isonitroso-, 1185.
 Hydroxyvaleric acid, α -, conversion of, into the lactone, 1151.
 Hydroxyxanthenes, synthesis of, 1060, 1494.
 Hygric acid, 586.
 Hygrine and the products of its oxidation, 586.
 — constitution of, 587.
 Hypochlorous acid, detection of, in chlorine-water, 242.
 Hypophosphoric acid, estimation of, 243.
 Hypophosphorous acid, estimation of, 243.

I.

Ichthulin, 1389.
 Idocrase, composition of, 651.
Illicium anisatum, constituents of the fruits and seeds of, 957.
 Imides, action of hypochlorites and hypobromites on, 1216.
 Imido-ethers, action of secondary amines on, 37.
 — and their derivatives, 468.
 — from ortho- and para-ethoxybenzonitrile, 63.

- Imido-ethers from trimethylene cyanide, 61.
 — of hydroxypropionitrile and phenyl-hydroxyacetoneitrile, 62.
 Imido-group, reagent for, 49.
 Inanition, formation of glycuronic acid in, 1529.
 Indazine, 1047.
 Indazole, amido-, 312.
 — nitro-, 312.
 Indazole-derivatives, 312.
 — synthesis of, 723.
 Indene, 205.
 Indene hydroxybromide, 206.
 Indican, modification of Jaffe's test for, 248.
 Indigo, assay of, 1564.
 — and allied dyes, synthesis of, 311.
 — estimation of indigotin in, 1404.
 — synthesis of, from anilidoacetic acid, 206.
 — synthesis of, from phenylglycine, 75, 206, 311, 456, 928.
 Indigo-carmin, synthesis of, 1069, 1231.
 Indigo-red, in urine, 850.
 Indigotin, extraction of, from commercial indigo, 722.
 Indigotindsulphonic acid, synthesis of, 1069, 1231.
 Indirubin in urine, 850.
 Indole, constitution of, 1090.
 Induline group, 1044.
 Indulines, eurhodines, and safranines, reactions between, 1213.
 Infection, substances which favour, 100.
 Intestine, action of opium and morphine on, 852.
 Invertase, preservation of, TRANS., 47.
 Invertebrates, action of nicotine on, 485.
 Iodation in the aromatic series, new method of, 1197.
 Iodic acid, molecular refraction and dispersion of, in solution, TRANS., 591.
 Iodides, chlorides, and bromides, detection of, 495.
 — detection of chlorine and chlorides in presence of, 1288.
 Iodine, affinities of, in solution, 148.
 — bromine and chlorine, detection of, in presence of one another, 361.
 — change of the colours of solutions of, when heated, 139.
 — detection of traces of, in presence of much chlorine, 242.
 — estimation of, in urine, 1288.
 — molecular weight of, in solution, 260.
 — purification of, from chlorine, 392.
 — solutions, absorption spectra of, 274.
 Iodometry, potassium iodate as original standard for, 615.
 Ions, theory of dissociation into, and its consequences, 972.
 Ipecacuanha root, dextrose from, 1183.
 Iridioammonium compounds, 402, 1165.
 Iridium chloride, molecular refraction and dispersion of, in solution, TRANS., 595.
 Iridiumpentamine bromonitrite, 401.
 — bromosulphate, 404.
 — chloridide, 403.
 — chlorobromide, 403.
 — chloronitrate, 403.
 — chloronitrite, 403.
 — chlorosulphate, 403.
 — chloroxalate, 403.
 — nitrate, 1166.
 — platinochloride, 403.
 — tribromide, 404.
 — trichloride, 402.
 Iridiumaquopentamine bromide, 1166.
 — chloride, 1166.
 — nitrate, 1166.
 Iron, action of nitric acid on, 1426.
 — action of nitrosyl chloride on, TRANS., 660.
 — and aluminium oxides, alcohol method of estimating, in phosphates, 1188.
 — carbonic oxide, 1427, TRANS., 604, 1090.
 — carbonyls, 1428, TRANS., 604, 1090.
 — carburation of, by the diamond, 807.
 — densimetric estimation of phosphorus in, 961.
 — deposits of, in the tissues, 1274.
 — detection and estimation of small quantities of aluminium in, 501.
 — estimation of, in rock analysis, 708.
 — estimation of manganese in, 063.
 — estimation of phosphorus in, 363.
 — estimation of sulphur in, 1549.
 — excretion of, 1128.
 — in the liver and spleen, 848.
 — in what form is it absorbed?, 478.
 — molecular changes in, 1308.
 — native, of terrestrial origin, from Berezowsk, 1434.
 — oxide and alumina, estimation of, in phosphates, 114, 1138.
 — passive state of, 250, 1427.
 — pyrites containing nickel and cobalt, 1435.
 — — from Pennsylvania, 154.
 — refraction and dispersion of, 373.
 — separation of, from cobalt and nickel, 1139.
 — substitution of manganese for, in plant nutrition, 1394.
 — sulphate, influence of, on nitrification of, 1543.

Iron, volatile compounds of carbonic oxide with, 1428, TRANS., 604, 1090.
 — volatilisation of, in presence of carbonic oxide, 1430.
 Iron-gymnite from Styria, 21.
 Iron-ore, estimation of phosphorus in, 363.
 Isatin, action of hydrazine hydrate on, 1360.
 — conversion of tetrahydroquinoline into, 722.
 — preparation of, 909.
 Isatin-blue, 928.
 — brom-, 1491.
 Isindazole derivatives, new synthesis of, 1375.
 Isallylene, isomeric change in, 1330.
 — preparation of, 996.
 Isoamyl alcohol, action of iodine on, 656.
 — oxide, molecular refraction and dispersion of, TRANS., 295.
 Isoamylene and phenol, condensation of, 208.
 Isoamyl naphthalene, β -, 730.
 Isobenzile, 931.
 — new synthesis of, 932.
 Isobutaldehyde, dihydric alcohols derived from, 31.
 Isobutoxybenzaldehyde, trithio-, 1051.
 Isobutyl alcohol, action of iodine on, 656.
 — chloride, action of aqueous ammonia on, 817.
 — glutarate, 62.
 — iodide, molecular refraction and dispersion of, TRANS., 295.
 Isobutylacetamide, 538.
 Isobutylamine, 36.
 Isobutylene pyridine, α -, 81.
 Isobutylisophtallic acid, 1064.
 Isobutylisopropylethylene glycol, 31.
 Isobutyl-3'-isopropylquinoline, 2'-, reactions occurring in the synthesis of, 1102.
 Isobutylpropylethylmethylammonium chloride, optical isomerides of, 100.
 Isobutyric anilide, α -bromo-, 828.
 Isobutyryl- α -naphthol, 448.
 Isocamphols, influence of solvents on the rotatory powers of, 375.
 Isocamphopyric acid, TRANS., 651.
 Isocantharidic acid, 1244.
 Isocantharidin, 1248.
 Isocaproamide, 538.
 Isocinchonine, 1121.
 — and its derivatives, 538.
 Isocinnamic acid, conversion of cinnamic acid into, 200.
 Isocymene, 3 : 6-diamido-2 : 5-dibromo-para-, 1190.
 Isocymoquinol, dibromo-, 1200.

Isocymo-3 : 6-quinone, 2 : 5-dibromo-para-, 1200.
 Isodehydraetic acid, 172.
 Isodiethylcarbobenzoic acid, 913.
 Isodimethyldipropyldithioamide, 1008.
 Isodimethyl-trychnine, 1264.
 Isodurene, nitration of, 693.
 Isoeuxanthone, 1061.
 Isofencholeoxime, 219.
 Isogallic acid phenylhydrazide, 202.
 Isomaltosazone, 413.
 Isomaltose, 412, 413.
 Isomethylstrychnine, 1264.
 Isomorphism, 146.
 — detection of, 1151.
 — of sulphur, selenium, and tellurium, 1417.
 Isomorphous groups, 1152.
 Isonicotinic acid, action of sodium amalgam on, 734.
 Isophenanthroxyleneacetic acid, action of acetic anhydride on, TRANS., 13.
 Isophenanthroxyleneacetoacetic acid, TRANS., 11.
 — action of potash on, TRANS., 12.
 Isophthalic acid, disulpho-, 73.
 — anhydride, disulphamine, 74.
 Isopiperideine, 556.
 Isopiperonylacryl methyl ketone, 705.
 Isopropyl chloride, action of aqueous ammonia on, 413.
 — iodide, action of aqueous ammonia on, 413.
 Isopropylamines, 166.
 Isopropylbenzene, oxidation of, with chromyl chloride, 898.
 Isopropylbenzoylformic acid, 1060.
 Isopropylisophthalic acid, 1064.
 Isopropylnitramine and its derivatives, 167.
 Isopropylparatoluidine, TRANS., 34.
 Isopropylparatolynitrosamine, TRANS., 34.
 Isopropylphenylacetyl glycollic acid, 1060.
 Isopropylphenylanilidoacetic acid, 1060.
 Isopropylphenylbromacetic acid, 1060.
 Isopropylphenylethylacetic acid, 1060.
 Isopropylphenylethylglycollic acid, 1060.
 Isopropylphenylglycollic acid and its derivatives, 1059.
 Isopropylphenylisnitrosoacetic acid, 1060.
 Isopropylphenylmethylglycollic acid, 1059.
 Isopropyltoluene, para-, synthesis of, 1022.
 Isopropyltricarballic acid, 546.
 Isoquinoline, amidobromo-, 581.
 — bromo-, derivatives of, 580.

Isoquinoline, dibrom-, 581.
 — nitrobromo-, and its derivatives, 580.
 — substitution products of, 580.
 Isostrychnic acid, 1262.
 — — methiodide, 1263.
 Isotetretthyldithioxamide, 1008.
 Isothermals, theoretical and empirical, of mixtures, connection between, 375.
 Isothiocyanoethylsulphine, 893.
 Isovaleron, 891.
 Isovaleroquinhydrone, 900.
 Isovaleroquinol, 900.
 Isovaleryldextroecgonine, 476.
 Isoxazole, amido-, 1108.
 Isoxazoles, formation of, TRANS., 410.
 Iso-xylalpthalide, 201.
 Iso-xylalpththalmidine, 201.

J.

Jervine, 88.
 Juloles, 736.

K.

Kainite, synthesis of, 405.
 Kallilite, a new nickel ore, 1167.
 Kesso oil, 238.
 Kessyl acetate, 239.
 — alcohol, 239.
 Ketodihydroquinoline, tetrachloro-, 1251.
 — trichloro-, 1250.
 Keto- γ -methyljuloline, α -, 737.
 — derivatives of, 737.
 Ketones, action of hydrazine hydrate on, 1355.
 — action of zinc and ethyl chloracetate on, 169.
 — aliphatic, constitution of, 1181.
 — alkyl, from halogen derivatives of aromatic hydrocarbons, 911.
 — aromatic alkyl, 199.
 — — and their oxidation, 564, 1222.
 — — application of Perkin's reaction to, 1223.
 — asymmetrical, oximes of, 1235.
 — isonitroso-, action of hydroxylamine on, 287.
 — mixed fatty aromatic, oxidation of, 1864.
 Ketonic acids, α -, oximes of, 443.
 — β -, preparation of ethereal salts of, 1185.
 — ethers, β -, synthesis of, 41.
 Ketotetrahydrobenzoic acid, hexachloro-, 708.
 — — pentachloro-, 710.

Ketotetrahydroquinoline hydrate, tetrachloro-, 1252.
 Ketoximes, aromatic, action of nitric peroxide on, 315.
 — configuration of stereoisomeric, 440.
 — stereoisomeric, 445.
 Kidney, analysis of the liquid from a tumour of the, 852.
 Kidneys, effect of partial extirpation of, on nutrition, 1273.
 Kopsia, alkaloids from, 337.
 Korynite from Siegen, 1167.
 Kreittonite from Bodenmais, 527.
 Kryokonite from Greenland, 408.
 Kuro-moji oil, 464.
 Kusa-uzu, aconitine from, 91.

L.

Labradorite from the Lizard, 276.
 — preparation of, 22.
 Lacmoid, 241.
 Lactalbumin, 340.
Lactarius piperatus, fats obtained from, 606.
 — — sugars in, 103.
 — *vellerus*, fats obtained from, 606.
 Lactic acid, formation of, in muscles, 348.
 — — formation of, in the organism, 1125, 1392.
 — — in organs with impeded circulation and in hydrocyanic acid poisoning, 1126.
 — — new optically active modification of, 666.
 — — preparation of, 1454.
 — fermentation, action of mineral acids on, 488.
 — — influence of artificial gastric juice on, 488.
 Lactone formation in the case of hydroxyacids, velocity of, 822.
 Lactose, estimation of, 1143.
 Levosobrerol, TRANS., 317.
 Levoterebenthene, TRANS., 313.
 Lakes, coloured, formation of, 807.
 Land, clover, effect of artificial manuring on, 492.
 Langbanite, place of, in the mineral system, 1436.
 Lanolin, 97.
 Lanthanum, atomic weight of, 881.
 — oxide, 985.
 — salts, molecular refraction and dispersion of, in solution, TRANS., 595.
 Lapachic acid, derivatives of, 1289, 1494.
 Lapachone, condensation of, with thiophen, 1494.

Lard, analysis of, 130
 — and its adulterations, 1560.
Lana, hydrocyanic acid in the fruit of, 338.
 Lauric acid, bromo-, 1190.
 — — heats of combustion and formation of, 11.
 Laurotetamine, the active constituent of certain Lauraceæ, 337.
 Lead acetate, molecular refraction and dispersion of, in solution, *TRANS*, 595
 — action of nitrosyl chloride on, *TRANS*, 658.
 — and silver oxides, compounds of, *TRANS*, 1093
 — copper potassium nitrite, 1157.
 — effect of various metals on the freezing point of, *PROC*, 1890, 160.
 — electrolytic estimation of, as amalgam, 1553.
 — estimation of, by phosphomolybdic acid, 113
 — flux, estimation of small quantities of silver in, 1292
 — ores, assay of, by the cyanide process, 863, 962.
 — oxide, action of magnesium on, 802.
 — — hydrated, 644.
 — persulphate, *TRANS*, 782.
 — waste, assay of, 365
 — zinc, and silver, alloys of, 267.
 — — and tin, alloys of, 267
 Lead-tin alloys, melting points of, 644.
 Leaf-green, observations on, *TRANS*, 106.
 Leaven, yeasts from, 1532.
 Leaves, influence of internal causes on the presence of starch in, 604
 — formation and migration of carbohydrates in, 763
 — of *Maclura aurantiaca*, 490, 954
 Leech extract, effect of, on blood, 482.
 Lecithin in the liver, 1275.
 — preparation of, from plant seeds, 413.
 Lecithins, estimation of, in vegetable organisms, 511.
 — rôle of, in normal germination, 489.
 Lecture experiment Combustion of magnesium in water vapour, *PROC*, 1891, 20.
 — — Demonstration of the dissociation of ammonium chloride, 1415
 Leguminosæ, assimilation of nitrogen by, 607.
 — fixation of gaseous nitrogen by, 353
 — fungus-symbiosis of, 353
 — nitrogen assimilation of, 1533.

Lepidium sativum, influence of salt on the quantity of starch contained in the vegetating organs of, 1133.
 Lemons, essence of, 1496
 — — detection of oil of turpentine in, 1497.
 Lemon grass oil, 286.
 Lettsonite from Arizona and from Utah, 156.
 Leucæmia, excretion of uric acid and nitrogen in cases of, 483.
 Leucine, condensation of, with benzene-sulphonic chloride, 202
 — constitution of, 681
 Leucite, preparation of, 22
 Leucocythæmia, the blood in, 1124
 Leucocytosis, production of, in mammals, 1340
Leuconotis eugenifolia, alkaloid from, 336
 Levosin, a carbohydrate from cereals, 661
 Levulinic acid, 1337
 — — α -bromo-, 1187.
 — — dibromo-, 417.
 — — $\alpha\beta$ -dibromo-, 1187.
 Levulose, estimation of, 1143
 — refractive power of, 1000.
 — rotatory power of, 1178
 Levulosecarboxylic acid, derivatives of, 547.
 Levuloseoxime, 813
 Lichens, assimilation by, 1132
 Light, action of halogens on aromatic compounds in presence of, 598.
 — action of, on anethol, 1317.
 — action of, on organic compounds, 900
 — action of, on phosphorous oxide, *TRANS*, 1019.
 — action of, on pure ether in presence of moist oxygen, *TRANS*, 51
 — action of, on silver chloride, 1155, 1420, *TRANS*, 536.
 — chemical effects of, 965
 — decomposition of glutaric and succinic acids by, in presence of an uranium salt, 1013
 — decomposition of silver chloride by, *TRANS*, 536
 — influence of hydrochloric acid on the decomposition of chlorine-water by, *TRANS*, 539
 — measurement of the quantity of, that enters water, 2
 — phosphorescence of minerals under the influence of, 776
 Ligno-celluloses, action of nitric acid on, *PROC*, 1891, 61
 Lime in black ash, estimation of, 497.
 Limonene, 1083.
 — dihydrochloride, 1196.

Limonene tetrabromide, 1241, 1496.
 Linaloe oil, 540.
 Linalool, 540.
Lindera fericia, ethereal oil of, 464.
 Linkage, double, theory of, 1320.
 Liparites, eutaxitic glasses of, 649.
 Liquid, the specific gravity of, a function of its boiling point and molecular weight, 780.
 Liquids, atomic weights and densities of, 1315.
 — connection between the critical data of liquids and their chemical constitution, 380.
 — crystalline, 249.
 — data for the critical state of, 969.
 — effect of pressure on the electrical conductivity of, 250.
 — expansion of, 8.
 — free surface of, 1150.
 — instrument for comparing the refractive indices of, 959.
 — law of diffusion of, 383.
 — new method of determining the specific volume of, TRANS., 37.
 — opaque, burette float for, 1288.
 — pathological, analysis of, 851.
 — relations between the boiling points, molecular volumes, and chemical characters of, 379.
 Liquescope, 959.
 Lithionite-granites, 652.
 Lithium compounds, phosphorescence of, in vacua, 249.
 — estimation of, in mineral waters, 1292.
 — salts, magnetic rotation of, PROC., 1890, 142.
 — — molecular refraction and dispersion of, in solution, TRANS., 595.
 — spectrum of, 137.
 — zirconate, 1431.
 Litmus paper, neutral, 1549.
 Litre, the true, or Mohr's, for volumetric analysis, 1548.
 Liver, excretion of urea in diseases of the, 758.
 — formation of glycogen in, 1526.
 — influence of alkalis on the glycogen of, 758.
 — iron in the, 848.
 — lecithin in the, 1275.
 — so-called, of *Helix pomatia*, 235.
 Liver-cells, crystals in the nuclei of, 587.
 Lubricating oils, estimation of acidity in, 505.
 Lupeol, 551, 1446.
 Lupetidine and allied substances, relation between the physiological action and chemical constitution of, 854.

Lupetidylalkine, α -, 1119.
 Lupinidine from white lupines, 1521.
Lupinus luteus, composition of the seeds of, 1541.
 Luteochromium hydrogen nitrate, 1327.
 Luteocobalt hydrogen nitrate, 1327.
 Luteorhodium salts, 1325.
 — acid, 1327.
 Lutidine, TRANS., 177.
 Lutidonecarboxylic acid, 676, TRANS., 176.
 Lutidonedicarboxylic acid, 676.
 Lutidylalkine, α -, 1119.
 Luzonite from the Argentine, 1435.
Lycopersicum esculenta, composition of the fruit of, 955, 956.
 Lymph, effect of peptone on the clotting of, 481.
 Lymph, human, 755, 849.
 Lysatine, 95.
 Lysatinine, 95.

M.

Macassar oil, 1133.
Maclura aurantiaca, composition of the leaves of, 490, 954.
 Magdala-red, fluorescence of alcoholic solutions of, on heating, 139.
 Magnesium, action of ethyl iodide on, 683.
 — action of methyl iodide on, 683.
 — action of nitrosyl chloride on, TRANS., 656.
 — action of propyl iodide on, 684.
 — alkyl compounds of, 682.
 — chromites, basic, 987.
 — combustion of, in water vapour, PROC., 1891, 20.
 — compounds of, with hydrocarbon radicles, experiments on the existence of, PROC., 1891, 16.
 — cyanogen compounds of, 1442.
 — dimethyl, 683.
 — ethyl attempts to prepare, PROC., 1891, 17.
 — hydride, 1156.
 — lead chloride, 151.
 — oxalate in plants, 857.
 — oxide, action of magnesium and hydrogen on, 1156.
 — — dissociation of, by means of metallic magnesium, 643.
 — — reduction of oxygen compounds by, 801, 1155.
 — salts, magnetic rotation of, PROC., 1890, 142.
 — — molecular refraction and dispersion of, in solution, TRANS., 595.
 — selenites, 262.
 — spectrum of, 1.

Magnetic field, influence of temperature and state of aggregation on the behaviour of bismuth in, 779.
 — rotation, TRANS., 198.
 — — of saline solutions, PROC., 1890, 141.
 — rotatory power of solutions of ammonium and sodium salts of some fatty acids, TRANS., 981.
 Magnetism and atomic weight, relation between, 518.
 — effect of, on chemical action, 1145.
 Magnetite ore districts in Brazil, 994.
 Maize cobs, xylose from, 1001.
 — dried in the field and as silage, 359.
 — green, growth of, 1395.
 Malacolite from the Lizard, 276.
 Maleic acid, action of bromine on, 39.
 — — conversion of, into fumaric acid, 1338.
 — — homologues of, 292.
 Maleinamic acid, 176.
 Maleinamyl chloride, dichloro-, 1047.
 — diethyl ether, dichloro-, 1048.
 — dimethyl ether, dichloro-, 1048.
 Maleinanilic acid, 176.
 Malic acid, combination of, with alkaline phosphomolybdates, 545.
 — — combination of, with potassium sodium molybdate and with acid sodium molybdate, 291.
 — — estimation of, in wine, 128, 371.
 — — homologues of, 1455.
 Malonic chloride, thermochemistry of, 867.
 Malt, non-nitrogenous extract-substance from, 957.
 Maltose, estimation of, 1143.
 — estimation of, in wort and beer, 368.
 — estimation of, with potassium cuprocarbonate solution, 1208.
 Mammals, production of leucocytosis in, 1340.
 Mandelic acid, iodo-, 831.
 — anilide, 438.
 Manganese, action of nitrosyl chloride on, TRANS., 660.
 — and zinc, separation of, 963.
 — ammonium ferrocyanide, 1293.
 — deposits in marine muds, 995.
 — dioxide, anhydrous and hydrated, 270.
 — estimation of, in iron and steel, 963.
 — estimation of, in ores, slags, &c., 366.
 — ore in Ekaterinoslav, 648.
 — ores of Transcaucasia, 647.
 — precipitation of, as ammonium manganous phosphate, 1188.

Manganese, selenites, 262.
 — substitution of, for iron in plant nutrition, 1394.
 — volumetric estimation of, 962, 1293.
 Mangano-magnesian magnetite, 274.
 Manganopectolite from Arkansas, 407.
 Mangold, experimental plots of, at Grignon in 1890, 493.
 Mannitol, fermentation of, with Friedlander's *Pneumococcus*, TRANS., 256.
 — in mushrooms, 103.
 — molecular refraction and dispersion of, in solution, TRANS., 591.
 — oxidation of, by nitric acid, TRANS., 306.
 — rotatory power of compounds of, with acid molybdates, 1443.
 Mannitol, d- and l-, configuration of, 1176.
 Mannosaccharic acid, d-, 678, TRANS., 306.
 — — phenylhydrazides of, 679.
 Mannosaccharic acid, i-, 679.
 Mannosaccharic acids, d- and l-, configuration of, 1176.
 Mannosaccharodiamide, d-, 679.
 Mannoseoxime, 665.
 Mannoses, d- and l-, configuration of, 1176, 1445.
 Mannoso-cellulose, 1179.
 Manure, depreciation of, by exposure to wet and fermentation, 1396.
 Manures, estimation of the total phosphoric acid in, 1397.
 — loss of nitrogen in the decomposition of, 1548.
 — nitric and ammoniacal nitrogen as, 1545.
 Manuring, artificial, effect of, on clover land and meadows, 402.
 — experiments with rice, 1547.
 Margarin, addition of phenolphthalein to, 872.
 — analysis of, 506.
 — and butter, discrimination of, 130.
 — detection of, in butter, 1300.
 Mass action, 1150.
 — influence of, on chemical processes, 257.
 Massoyene, 464, 935.
 Meadows, effect of artificial manuring on, 492.
 Melanin, artificial, 1123.
 — as a precursor of hæmoglobin, 480.
 Melanite from the Kaiserstuhl, 651.
 Melanophlogite, 648.
 Melidoacetic acid, derivatives of, 162.
 Meli-se oil, German, 540.
Melodinus lasigatus, alkaloid from, 336.

- Melon seeds, presence of cholesterol and a soluble carbohydrate in, 357.
- Membranes, precipitated, electrical conductivity of, 140, 517.
- Men, healthy, proteid requirement of, 1272.
- Mentha pulegium*, oil of, 936.
- Menthyl, molecular refraction and dispersion of, in solution, TRANS., 591.
- Mercaptan, amido-, hydrochloride, 815.
- and sodium benzenesulphinate, action of iodine on a mixture of, 924.
- Mercaptans, aromatic, synthesis of, 1350.
- Mercaptopropylphthalimide, β -, 1473.
- Mercurammonium iodides, 270.
- nitrates, 268.
- sulphates, 269.
- Mercuric chloride, poisoning by, 853.
- chlorides, ammoniacal, 985.
- cyanide, action of ammonia on, 1441.
- — ammoniacal derivatives of, 655.
- — combination of, with cadmium salts, 161.
- — combinations of, with lithium salts, 28.
- fulminate, action of benzoic chloride on, 64.
- oxide and potassium chloride, reaction between, 1413.
- sulphide, separation of, from the sulphides of the arsenic and copper groups, 1292.
- Mercury, action of nitrosyl chloride on, TRANS., 659.
- arsenates, 400.
- barium chlorocyanide, action of ammonia on, 1442.
- cadmium iodoecyanide, action of ammonia on, 1441.
- compounds, ammoniacal, so-called, 268.
- conditions of action of nitric acid on, 525.
- detection and estimation of, in corpses, 120.
- detection and estimation of, in organic mixtures, 351.
- detection of, in toxicological investigations, 864.
- development of electromotive force between an electrolyte and, 374.
- electrolytic estimation of, 1553.
- estimation of, in animal tissues, 962.
- magnesium bromocyanide, 1442.
- — iodoecyanide, 1442.
- phosphates, 400.
- salicylates, absorption of, 351.
- Mercury, specific heat of, 632.
- vapour pressures of, TRANS., 629.

- molecular condition of, when alloyed with each other, PROC., 1890, 158.
- refraction and dispersion in, 373.
- Metaphosphates, isomerism of, 7.
- Metaphosphoric acid, molecular refraction and dispersion of, in solution, TRANS., 593.
- Meteoric iron from Bridgewater, Burke Co., North Carolina, 278.
- — from Hamilton Co., Texas, 277.

Meteoric iron from Henry Co, Virginia, 159.

— from Magura, Arva, Hungary, 27.

— from North Dakota, 531.

— from Puquion, Chili, 277.

— from Rockingham Co., North Carolina, 159.

— from Summit, Blount Co., Alabama, 279.

— stone from Haywood Co., North Carolina, 278.

Meteorite from Collescipoli, 533.

— from Eli Elwah, New South Wales, 279.

— from Gilgoi, New South Wales, 279.

— from Pipe Creek, 532.

— from Thunda, Queensland, 279.

— from Winnebago Co., Iowa, 278.

— of Oehansk, 532.

Meteorites from Barratta, New South Wales, 279.

— from Brenham Township, Kiowa Co., Kansas, 278.

Methacrylic anilide, 828.

Methæmoglobin, conversion of carboxy-hæmoglobin into, 1522.

Methamidobenzmethylamide, nitro-, 917.

Methamidobenzoic acid, nitro-, 916.

Methane, nitro-, action of alkalis on, TRANS., 430.

— action of, on animals, 1393.

Methanedisulphonic acid, action of nitric acid on, 426.

Methanetriquinol, 1261.

Methanetrisulphonic acid, action of nitric acid on, 426.

Methenylamidinephenylmetacarboxylic acid, 304.

Methoxybenzaldehyde, paranitro-, preparation of, 703.

Methoxybenzaldehydes, trithiopara-, 1050.

— trithiortho-, 1051.

Methoxybenzophenone and its ketoximes, 445.

Methoxycarbostyryl, 1101.

Methoxycinnamic acid, orthonitrometa-, 1101.

Methoxydihydroxydihydroquinoline, 1098.

— para-, 1101.

Methoxyisoxazoledicarboxylic acid, 739.

Methoxyl, interference of substances containing sulphur with Zeisel's method for the estimation of, 1296.

Methoxynaphthaphenazine, 1213.

Methoxyphenylglyoxylic acid, para-, 711.

Methoxyphenyllactic acid, orthonitrometa-, 1100.

Methoxyphenyl-*ald*-phenylnaphthotriazine, *az*-ortho-, TRANS., 697.

Methoxysuccinamide, TRANS., 470.

Methoxysuccinic acid, TRANS., 471.

Methyl acetylamidoformate, 292.

— acrylate, action of methyl alcohol on, TRANS., 474.

— alcohol solutions, specific heats of, 1406.

— allocinnamate, 833.

— amidobenzoate (ortho-), action of ammonia on derivatives of, 912.

— amidoformate, action of nitrous acid on, 292.

— carbonate, action of potassium ethoxide on, 1014.

— chlorethyl ketone, 1183.

— chlorovinyl orthodiketone, dichloro-, 690.

— crotonate, action of methyl alcohol on, TRANS., 476.

 — 8-, 1257.
 Methylquinone chlorimide, 187.
 Methylresorcinolphthaloylic acid, 70.
 Methylrosindulone, 1213.
 Methylsaccharin, 1228.
 Methylsalicylalcamphor, 1498.
 Methylsaligenylcamphor, 1499.
 Methylstrychnic acid methiodide, 1263.
 Methylstrychnine, 1263.
 "Methyltetrahydroperichinaldimidazole, α -" 1256.
 Methyltetrahydropyridylacetylene, 67.
 Methyltetrahydropyridylethylene, ω -bromo-1:3:4-, 66.

- Methyltetrahydropyridyl- β -hydroxypropionic acid, 333.
 Methylthebainium sulphate, physiological activity of, 762.
 Methylthiazole- β -carboxylic acid, μ -, 224.
 Methylthiazolecarboxylic acid, μ -, 224.
 Methylthiazoline, μ -, 817.
 Methylthiazoline, μ -imido- n -, 1515.
 Methylthiazolinehydrazine, n -, 1516.
 Methylthiazylacetic acid, 743.
 Methylthiosinamine, 549.
 Methyltolyl methyl ketone, meta-bromortho-, 911.
 ———— meta-chlorortho-, 911.
 ———— orthobromometa-, 911.
 ———— orthochlorometa-, 911.
 Methyltricarballic acid, 546.
 Methylumbelliferonecarboxylic acid, β -, 672.
 Methyluracil, imido-, and its derivatives, 1007.
 Mica, composition of, 530.
 ———— from Haddam, Connecticut, 531.
 ———— from Salm-Chateau, Belgium, 528.
 ———— from Zinnwald, 531.
 Microbe, nitric, 1545.
 ———— of blenorrhagic pus, toxalbumin secreted by, 1521.
 Microbes, secretions of, 1132, 1394.
 Microchemical mineral analysis, 766.
 Micro-organisms, reducing power of, 102.
 Milk, action of calcium salts on, 340.
 ———— analysis, asbestos method of, 1299.
 ———— citric acid a normal constituent of, 1276.
 ———— detection and estimation of boric acid in, 619.
 ———— elephant's, 98.
 ———— estimation of casein in, 1404.
 ———— estimation of citric acid in, 1276.
 ———— estimation of fat in, 508, 509, 625, 1299, 1402, 1559.
 ———— estimation of sugar in, 127.
 ———— of cows, composition of the, during early and late periods of lactation, 97.
 ———— of hill-bred cows, amount of fat and dry matter in, 1275.
 ———— origin of citric acid in, 1276.
 ———— peptonised, proteids of, 953.
 ———— proteids of, 339, 951.
 ———— sheep's, 951.
 ———— sterilisation of, 603.
 Milk-sugar, estimation of, 1298.
Milletia atropurpurea, poisonous glucoside from, 335.
 Mineral condensation, coefficient of, in chemistry, 258.
 ———— water of Penon de los Banos, Mexico, 279.
 Mineralogical notes, 1435.
 Minerals, estimation of water in, 766.
 ———— from Corsica, 1440.
 ———— influence of fluorine in the synthesis of, 21.
 ———— of Port Henry, New York, 158.
 ———— phosphorescence of, under the influence of light and heat, 776.
 Molasses, estimation of invert sugar in, 769.
 Molecular changes in metals as shown by their electrical conductivity, 1308.
 ———— conductivity of acids in various solvents, 1308.
 ———— refraction of carbon compounds, TRANS., 290.
 ———— of substances containing nitrogen, 373.
 ———— theory and electrolytic dissociation, 390.
 ———— volumes, boiling points, and chemical characters of liquids, relations between, 379.
 ———— calculation of, 1408.
 ———— of acetic acid, TRANS., 903.
 ———— of carbon tetrachloride and stannic chloride, TRANS., 911.
 ———— of the saturated vapours of benzene and its halogen derivatives, TRANS., 125.
 ———— weight and rate of evaporation, connection between, 1316.
 ———— determination of, at the critical point, 1411.
 ———— of sulphur dichloride, 149.
 ———— weights, determination of, by a cryoscopic method, 380.
 ———— determination of, by the ebullition method, 389, 1317.
 ———— direct comparison of the physical constants involved in the determination of, by Raoult's method, PROC., 1891, 26.
 ———— of gallic and tannic acids, 145.
 ———— of metals in solution, PROC., 1890, 159.
 ———— of some metals, 984.
 ———— of sulphur, phosphorus, and iodine in solution, 260.
 Molisch's reactions, new applications of, 128.
 Molybdates, acid, rotatory power of compounds of mannitol with, 1443.
 Molybdenite, artificial preparation of, 20.
 Molybdenum, new oxygen compound of, 988.
 ———— proportion of, in scheelite, 406.
 Molybdovanadates, 884.
 Monazite from Sweden, 1168.
 Monticellite from Magnet Cove, Arkansas, 1330.

Mordants and the periodic law, 523
 Mordenite 276
 Morphine, action of, on the intestine, 852
 — derivatives of, 332
 — effect of, on cats 486
 — estimation of, 771, 1408
 — estimation of, in opium 511
 — fate of, in the animal organism, 479
 — reaction for, 1562
 — violet colouring matter derived from, 1120
 Morphotropy, 146
Morrena brachystephana, constituents of, 1122
 Morrenine 1122
 Morrenole, 1088
 Mucic acid, TRANS, 750
 — action of phosphorus pentachloride on, TRANS 26
 — constitution of, TRANS, 753
 — lactone acid of, 1194
 — new isomeride of, 1193
 Mucin albumose, 1127
 Mucoid 1127
 Mucoid substance in acetic fluid, 1127
 Muconic acid, TRANS, 750
 — action of bromine on, TRANS, 750
 Mud, analyses of, 958.
 — from deep seas, composition of, 995
 — marine, manganese in, 995
 — occurrence of sulphur in, and its bearing on their modes of formation, 994
 Muscle activity, effect of increase on the decomposition of albumin, 1524
 — nutrition of, 1273
 Muscles, formation of lactic acid in, 348
 Muscovite from Bamle, Norway, 531
 Muscular work and proteid metabolism, 596, 847
 — influence of, on proteid metabolism, 479
 — influence of, on the output of urea, 350
 Mushrooms, sugars in, 103
 Musk, artificial, 1464
 Mustard, essential oil of, 818
 Myelin, 846
 Myohæmatin, 478
 Myosin, digestion of, 950.
 Myosin peptone, 950
 Myristic acid, heats of combustion and formation of, 11
 Myriobalans, tannin of, 918.
 Myrtle, essence of, 1384

N.

Naphthaenodole, α , modifications of, 1214
 Naphthalene, α bromo, optical properties of, 776
 — β bromo- preparation of, 553
 — constitution of, 44
 — constitution of the tri derivatives of, PROC 1891 27
 — 1 3' dibromo, 461
 — 1 3' 2 dibromochloro, 462
 — 1' 4 2 dinitramido, 321
 — dithiocynate 460
 — 1 2 3' tribromo, 461
 — 2 1' 4' trichloro, 463
 Naphthalenesulphonamide, 1 3' amido, 573
 — 1 3' nitro, action of hydriodic acid on 573
 Naphthaloxazine, 1342
 Naphthaquinaldine β , octohydro derivatives of, 1513
 — tetrahydro derivatives of, 1510
 Naphthaquinol 3 bromo 1 2, 462
 Naphthaquinoline, α , preparation of, 1258
 Naphthaquinoline, β , octohydro derivatives of, 1511
 — tetrahydro derivatives of, 1510
 Naphthaquinolines, reduction of, 1258
 Naphthaquinone, 3 bromo 1 2, 462
 Naphthaquinone hydrazones, β , 1074
 — phenylhydrazone, β , constitution of, 1076
 Naphthaquinonehydrazonobenzoic acid, β , action of diazobenzene chloride on 1075
 Naphthaquinonehydrazonophenylamine acid, β , action of diazobenzene chloride on, 1075
 Naphthasulphon sulphonic acid, β , 215
 — acids, 215
 Naphthazinehydroxycarboxylic acid, 1312
 Naphthol acid, β -, amido 932
 — chloro- and nitro derivatives of, 932
 — 1, 3' dibromo, 462
 — nitramido, 79
 — nitro, 78, 79
 — acids, 77, 932
 — hydrogenation of, 1380.
 — diamido β , 78, 79
 — dinitro β , 78
 Naphthol, passage of, into the urine, 98
 Naphthol, α , orthoaro compounds of, 1074
 — disulphide, 322
 Naphthol, β , bisulphide, 321.

- Naphthol, β -, bromo-derivatives of, *Proc.*, 1891, 87.
 — 1 : 3-bromochloro- β -, *Proc.*, 1891, 33.
 — di- and tri-chloro- β -, *Proc.*, 1891, 32, 33.
 — 1 : 3-dibromo- β -, *Proc.*, 1891, 33.
 — nitroso- β -, action of, on animals, 1393.
 — tetrabromo- β -, *Proc.*, 1891, 88.
 — tribromo- β -, *Proc.*, 1891, 87.
 — β -, sulphides of, 320.
 Naphthol-derivatives, nitration of, *Proc.*, 1891, 89.
 Naphtholphthalein anhydride, 1029.
 Naphthols, chloro- and bromo-, action of nitric acid and oxidising agents on, *Proc.*, 1891, 34.
 Naphtholsulphonamidodisulphonic acids, α -, 215.
 Naphtholsulphonic acid, amido-, 215.
 Naphthol-violet, action of aromatic bases on, 77.
 Naphthoutrile, 1 : 3'-dibromo-, 462.
 Naphthoutrile, β -, nitro- and chloro-derivatives of, 932.
 Naphthoylformic acid, β -, 214.
 Naphthyl ethyl ether, dinitro-, 321.
 — methyl ketones, 214.
 — sulphides, 76.
 Naphthyl glycidyl ether, α -, 1199.
 Naphthyl benzenesulphonate, β -, 369.
 — ethyl ether, β -, nitro- and amido-derivatives of, 459.
 — methyl ketone, β -, 729.
 — phenyl ketone, β -, boiling point of, 1240.
 Naphthylacetic acid, β -, 215, 730.
 Naphthylallylsemithiocarbazide, β -, 550.
 Naphthylamidobenzoic acid, metanidopara-, α -, 307.
 — — — metanitropara-, α -, 307.
 Naphthylamidobenzoic acid, metanitropara-, β -, 307.
 Naphthylamidoethylphthalimides, α - and β -, 1208.
 Naphthylamine, α -, action of picric chloride on, *TRANS.*, 716.
 Naphthylamine, β -, azo-derivatives of, *TRANS.*, 372.
 — β -, bromo-derivatives of, 461.
 — β -, chloro- and bromo-derivatives of, *Proc.*, 1891, 32.
 — 1' : 4'-dichloro- β -, 462.
 — tribromo- β -, 462.
 Naphthylaminebenzylidenesulphonic acid, α -, sodium salt of, 720.
 Naphthylaminedisulphonic acid, β -, Andersen's, *Proc.*, 1891, 27.
 Naphthylazoacetic acid, α -, 1382.
 Naphthylazoacetoacetic acids, α - and β -, 1381.
 Naphthylazoacetone, α -, 1382.
 Naphthylbenzylxythiocarbamide, α -, 559.
 Naphthylcyanamide, α -, 559.
 Naphthylene dihydrosulphide, 460.
 — mercaptan, 460.
 Naphthylenediaminedisulphonic acid, ortho-, derivatives of, 210.
 Naphthylglycollamide, β -, 729.
 Naphthylglycollic acid, α -, 730.
 Naphthylglycollic acid, β -, 215, 729.
 Naphthylglyoxylic acid, β -, 214.
 Naphthylhydroxythiocarbamide, α -, 558.
 Naphthylmethylparazoloneketone- α -naphthylhydrazone, α -, 342.
 Naphthyl-*al*-phenylnaphthotriazine, α - β -, 698.
 Naphthylpropylene pseudosemthiocarbamide, β -, 550.
 Naphthylsulphonamic acid, β -, ammonium salt of, 569.
 Narcosine, reaction for, 1562.
 Narcotine, physiological activity of, 762.
 — reaction for, 1562.
 Natrolite, 1438.
 — of Montecatini, 1438.
 Nepheline, preparation of, 22.
 Nepheline-syenite of the Kola Peninsula, 531.
 Nerve fibres and cells (peripheral), action of poisons on, 185.
 Nickel, action of nitrosyl chloride on, *TRANS.*, 660.
 — alloys, molecular changes in, 1308.
 — and cobalt, separation and estimation of, 1139.
 — — — separation of iron from, 1139.
 — carbon oxide, physical properties of, 1322.
 — — — physiological action of, 1130.
 — — — properties of, 1428.
 — dextroate, *TRANS.*, 323.
 — electrolytic separation of gold from, 1396.
 — molecular changes in, 1308.
 — native, in river sand near Biella, Piedmont, 526.
 — ores from New Caledonia, 157.
 — refraction and dispersion of, 373.
 — selenites, 262.
 — volatilisation of, in presence of carbonic oxide, 1429.
 — volatility of, in presence of hydrogen chloride, 1429.
 Nicotine, 945.
 — action of benzoic chloride on, 945.
 — action of, on invertebrates, 453.
 — action of, on the heart and blood vessels, 96.

- Nicotine, constitution of, 583.
 — estimation of, in presence of ammonia, 771.
 — in tobacco plants, climatic conditions for the development of, 858.
 — oxidation of, with hydrogen peroxide, 473.
 Nicotinic acid, action of sodium amalgam on, 733.
 Nipicotinic acid, 735.
 Nitrates and ammonium salts as manures, 1545.
 — cinchonamine as a test for, 362.
 — detection of, in wine, 961.
 — estimation of, by the phenolsulphonic acid method, 1136.
 — estimation of, in potable waters, TRANS., 320.
 — estimation of nitrogen in, by Kjeldahl's method, 1397.
 — formation of, in soils, 1395.
 — iodometric estimation of, 618.
 — iodometric estimation of nitric acid in, TRANS., 530.
 — loss of, by soils, 765.
 — magnetic rotation of, PROC., 1890, 144.
 — production of, in nitrification, TRANS., 514.
 — value of, as food for ferments and other plants, 1135.
 Nitration of benzenoid derivatives, PROC., 1891, 89.
 — with nitric peroxide, PROC., 1891, 91.
 Nitric acid and certain metals, conditions of change between, 525.
 — — detection of, in wine, 1551.
 — — estimation of, by reduction to ammonia, 617, 690.
 — — estimation of, in potable waters, 496.
 — — iodometric estimation of, in nitrates, TRANS., 530.
 — — molecular refraction and dispersion in solution, TRANS., 593.
 — — nitrogen, estimation of, by aluminium, 617.
 — — loss of, in drainage water from different crops, 859.
 — — organism, behaviour of, with ammonia, TRANS., 521.
 — — nutrition of, TRANS., 519.
 Nitrides, action of hydroxyhydrocarbon derivatives of, 1003.
 Nitrification, 102, TRANS., 484.
 — a purely nitrous agent of, TRANS., 486.
 — conditions which determine the formation or separation of a nitrous agent only, TRANS., 490.
 Nitrification, distinction between the production of nitrites and nitrates in, TRANS., 485.
 — in soils, 101.
 — influence of iron and calcium sulphates on, 1543.
 — isolation of the nitrous organism, TRANS., 495.
 — nutrition of the nitric organism of, TRANS., 519.
 — nutrition of the nitrous organism of, TRANS., 509.
 — production of nitrates in, TRANS., 514.
 — the ferment of, 352.
 — theory of, TRANS., 523.
 Nitrites, action of boron fluoride on, 1441.
 — action of, on organic acids, 409.
 — conversion of, into imido-ethers, 59.
 — formation of, in oxidations with nitric acid, 812.
 — β -ketonic, action of aromatic amines on, 51.
 — synthesis of, 41.
 Nitrites, formation and oxidation of, in soils, 1545.
 — paraffinic, action of, on blood pressure, 1270.
 — production of, in nitrification, TRANS., 486.
 Nitro-compounds of the paraffin series, action of alkalis on, TRANS., 410.
 Nitro-derivatives, new method of preparing, PROC., 1891, 91.
 Nitrogen, assimilation of, by beans, 1539.
 — assimilation of, by Leguminosae, 353, 607, 1533.
 — assimilation of, by plants, 855.
 — assimilation of, from the air by *Robinia pseudacacia*, 764.
 — atmospheric, acquisition of, by plants, 353, 491.
 — density of, 1416.
 — estimation of, by the Schulz-Tiemann method, 107.
 — estimation of, in nitrates, by Kjeldahl's method, 1397.
 — estimation of, in organic substances, by means of alkaline permanganate, 109.
 — estimation of, in pickled railway sleepers, 620.
 — estimation of, in sodium nitrate, 107.
 — excretion of, in cases of leucæmia, 483.
 — excretion of, in the sweat, 350.
 — gaseous, fixation of, by Leguminosae, 353, 607, 1533.

Nitrogen, hydride, 394.
 — increased output of, in cerebral hyperthermia, fever, and artificial overheating, 600.
 — Kjeldahl's process for the estimation of, 862.
 — loss of, in the decomposition of manures, 1548.
 — molecular refraction of substances containing, 373.
 — nitric and ammoniacal, as manures, 1546.
 — — estimation of, as nitric oxide, 107.
 — — estimation of, by aluminium, 617.
 — occurrence of, in uraninite, 527.
 — peroxide, liquid, dissociation of, TRANS., 1076.
 — — preparation of, TRANS., 1077.
 — — use of, as a nitrating agent, PROC., 1891, 91.
 — spectrum of, 1.
 — the Kjeldahl-Wilfarth method of estimating, 362.
 Nitrogen-atom, asymmetrical, possibility of existence of, 51.
 Nitrogen-compounds, attempts to prepare stereochemical isomerides of, 35.
 — — in vegetable soils, 610.
 — — nomenclature of those containing two nitrogen atoms linked together, 1350.
 — — stereochemical isomerides of, 34.
 — — volatile, evolved from vegetable soils, 611.
 Nitrogenous substances in barley, change in, during germination, 489.
 — — of arable soil, 492.
 Nitro-hydrocarbons of the fatty series, tertiary, 653.
 Nitro-keto-compounds, formation of, PROC., 1891, 39.
 Nitroprussides, preparation of, 410.
 Nitroso-compounds, preparation of, 688.
 Nitrosyl chloride, action of heat on, 73, TRANS., 271.
 — — action of, on metals, TRANS., 655.
 Nitrous acid, estimation of, in potable waters, 496.
 — — velocity of decomposition of, in aqueous solution, 522.
 — — ether. methylated, detection of, 123.
 — — organism of nitrification, isolation of, TRANS., 495.
 — — — description of, TRANS., 507.

Nitrous organism of nitrification, nutrition of, TRANS., 509.
 — — — properties of, TRANS., 505.
 Nodules, marine, occurrence of sulphur in, and its bearing on their modes of formation, 994.
 — — root, of the pea, 607.
 Nonarabinantetragalactangeddic acid, TRANS., 1071.
 Non-electrolytes, nature of chemical change in, PROC., 1891, 118.
 Nononaphthene and its derivatives, 184.
 Nononaphthyl alcohol, 185.
 Nononaphthylene, 185.
 Notochord, chemical composition of, 1126.
 Nuclei of liver cells, crystals in, 587.
 Nuclein of yeast, metaphosphoric acid in, 477.
 Nutrition, effect of partial extirpation of the kidneys on, 1273.
 — — of muscle, 1273.

O.

Oak-tannic acids, 70.
 Oak-wood, tannic acid of, 1061.
 Oat-kernel, proteins of the, 1285, 1890.
 Obituary notices, TRANS., 452.
 Obsidian cliff, Yellowstone National Park, 26.
 Ochroleite from Fajersberg, 1168.
Ochroa acuminata, alkaloids from, 337.

 Osotriazolecarboxylic acid, 1117
 Osotriazoles, formation, properties, and constitution of, 1110
 Oxalacetates, action of carbonyl chloride on, 1333
 Oxalacetophenylimide, sodium derivatives of, 903
 Oxalates, ethereal action of sodium methoxide on, 1014
 Oxalenediamidines, bisubstituted, constitution of. 697

Oxalenedihydrazoximediethylidene 698.
 Oxaleneperatolyamidineamidoxime, 698.
 Oxaleneperatolyldiamidodioxime, 698.
 Oxalic acid, action of, on barium chloride, 377.
 — and its homologues, thermochemistry of, 968.
 — ferment, 857.
 Oxalic series of acids, distillation of the potassium hydrogen salts of, 1011.
 — — electrolysis of ethyl potassium salts of the, 1192.
 Oxaluric acid, thermochemistry of, 1449.
 Oxamethanetoloxamide, 908.
 Oxides of the heavy metals and alkali halides, reaction between, 1413.
 — reduction of, with magnesium, 1155.
 Oximes, 1181.
 — asymmetrical, which do not form stereometric isomerides, configuration of, 442.
 — formation of, 36.
 — isomeric, constitution of, 1354.
 — isomerism of, 35, 823.
 — of aldehydes and α -ketonic acids, 443.
 — stereoisomeric, spacial configuration of, 439.
 Oxazo-derivatives, action of phosphoric chloride on, 556.
 Oxydigitogenic acid, 577.
 Oxygen, active, metaphenylenediamine as a test for, 1289.
 — and carbonic anhydride, simultaneous evolution of, by *Cactæ*, 856.
 — and hydrogen, admixed, slow combustion of, 1153.
 — atmospheric, utilisation of, 392.
 — atomic weight of, 1154.
 — available in peroxides, estimation of, 1136.
 — compressibility of, 378.
 — density of, 1416.
 — dissolved in water, estimation of, 616.
 — gasometric estimation of, 616.
 — in air, Priestley's method of estimating, 362.
 — in the blood, estimation of, 845.
 — in the blood of animals at great altitudes, 753.
 — liquid, absorption spectrum and colour of, 773.
 — solubility of, in water and alcohol, 15.
 — the specific quantities of, in blood, 244.

Oxygen-compounds, reduction of, by magnesium, 801.
 — reduction of, with sodium, 150.
 Oxyhæmoglobin in bile, 599.
 — preservation of, 591.
 Oxylepidens, action of ammonia and methylamine on, TRANS, 140.
 Oxymetatuquinoline, nitroso-ortho-, 826.
 Oxymethylquinoline, nitroso-ortho-, 327.
 Oxynicotine, 473.
 Oxyparatoluquinolineoxime, 326.
 Oxypentic acid, 1221.
 Oxypyridine bases, synthesis of, 1092.
 Oxyquinolines, nitroso-, tinctorial properties of, 579.
 Oxysparteine, 842.
 Oxytetrazotic acids, 1038.
 Oxytetric acid and its homologues, 1187.
 — acids, real nature of, 1188.
 Ozokerite, complete chlorination of, 812.
 Ozone, formation of, in flames, 798.
 — therapeutic and physiological effects of, 1531.

P.

Pachyrhizus angulatus, poisonous principle from, 335.
 Paints, estimation of turpentine in, 1302.
 Palladio-ammonium chloride, action of hydrogen sulphide on, 272.
 Palladium, electrolytic estimation of, 1140.
 — separation of gold from, 1396.
 Palmelline, 845.
 Palmitanilide, 821.
 Palmitic acid, α -amido-, 820.
 — — α -bromo-, 820.
 — — complete chlorination of, 811.
 — — derivatives of, 820.
 — chloral, 535.
 Pancreatic digestion, action of bile on, 96.
 — juice, influence of bile on the fat-splitting properties of, 948.
 — extract, action of, on casein, 1272.
Pangium edule, free hydrocyanic acid in, 338.
 Papaverine, reaction for, 1562.
 Papaveroline, 85.
 Parabanic acid, thermochemistry of, 1449.
 Paracrylic acid, 170.
 Paraffin, stearin, stearic acid, and wax, analysis of a mixture of, 1400.
 Paraffins, normal, calculation of the melting and boiling points of, 1380.

- Paraldehyde, relation between the spectro-metrical constants and chemical constitution of, 630.
 Paramuric acid, so-called, 1193.
 Paraphytosterol, 606.
 Pararosaniline, condensation of, with aldehyde, 1071.
 Paratropine and its derivatives, 1093.
 Paraxanthine, 1120.
 Passive state of iron and steel, 250.
 Pea, root nodules of the, 607.
 Pectin, sugar from, 413.
 Pennine from Zermatt, 531.
 Pentaglucozes, 411.
 — estimation of, in vegetables, 768.
 Pentahydroxyanthraquinoline, 1240.
 Pentallylcarbimdimethylamine, 1508.
 Pentallylcarbimtrimethylammonium iodide, 1508.
 Pentane, dibromo-, 162.
 — molecular refraction and dispersion of, TRANS., 205.
 — tetrabromo-, 534.
 — tribromo-, 534.
 Pentanetetracarboxylic acid, preparation and properties of, TRANS., 824.
 — synthesis of homologues of, TRANS., 818.
 Pentanetricarboxylic acid, 1 : 3 : 5-, 547.
 Pentarabinantetragalactangeddic acid, TRANS., 1070.
 Pentoses, 411.
 — estimation of, in vegetables, 768.
 Peonol, synthesis of, 1233.
 Peppermint, Russian oil of, spectroscopical properties of, 2.
 Pepsin, influence of temperature on, 1272.
 Peptone, effect of, on the clotting of blood and lymph, 481.
 — fate of, 479.
 — formation of, in gastric digestion, 953.
 Peptonised foods, 953.
 Peptotoxin, 1267.
 Perchloric acid, molecular refraction and dispersion of, in solution, TRANS., 593.
 Periclaso, artificial, 991.
 Peridotite from the Harz, 24.
 Periodic law and mordants, 523.
 — approximate algebraic expression of, 13.
 — relation of certain properties of metals to, 1161.
 — property of the elements, new, 12.
 Perkin's reaction, 69.
 Permanganates, titration of, with hydrogen peroxide, 246.
 Permolylbic acid, 988.
 Perovskite, so-called, from Magnet Cove, Arkansas, 529.
 Peroxides, estimation of the available oxygen in, 1136.
 — of the alkaline earths, estimation of, 245.
 Persulphates, TRANS., 771.
 Pertungstic acid, 988.
 Petroleum, Baku, acids from, 1452.
 — Caucasian, 185.
 — constitution of the oxygen compounds in, 999.
 — Ohio, sulphur compounds in, 1172.
 — Pennsylvanian, complete chlorination of, 811.
 Phakellite from Vesuvius, 22.
 Pharmacolite from Styria, 21.
Phaseolus vulgaris, constituents of the seed pods of, 606.
 — nitrogen assimilation of, 1538.
 Phasol, 606.
 Phellandrene, 1084.
 Phellonic acid, 465.
 Phenacyl sulphide, 302.
 Phenanthridine, 837.
 — methylhydroxide, 837.
 Phenanthroline bases, constitution of, 1258.
 Phenazines, 470.
 Phenazoxime, dinitro-, TRANS., 723.
 Phenethenylamidine phenethenyldioxy-tetrazotate, 1041.
 Phenethenyldioxytetrazotic acid, 1041.
 Phenetol, metanitropariodo-, 431.
 — tribromodinitro-, 1026.
 Phenetoltrimethylammonium iodide, amido-, 53.
 Phenethylindazole, 2'-para-, 724.
 Phenol, action of methylchloroform on, in presence of alkalis, 296.
 — chlorination and bromination of, PROC., 1891, 64.
 — condensation of metanitrobenzaldehyde with, 1346.
 — dinitrosonitro-, 688.
 — diorthonitro-, action of bromine on, PROC., 1891, 63.
 — estimation of, 155.
 — idiosyncrasy of certain animals with respect to, 762.
 — metanitroparamido-, and its derivatives, 430.
 — metanitropariodo-, 431.
 — metaparamido-, 431.
 — of birch-wood tar, 432.
 — parabromodiorthonitro-, isomeric change of, PROC., 1891, 63.
 — parachlorodiorthonitro-, PROC., 1891, 63.
 — red, colouring matter of, 1198.
 — sulphonation of, 391.
 — symmetrical dinitro-, 430.

- Phenol, tetrachloro-, 297, 710.
 Phenol-acenaphthene, dinitrosonitro-, 689.
 Phenol-anthracene, dinitrosonitro-, 689.
 Phenoldiammonium, 1860.
 Phenoldicarboxylic acids, preparation of, 1867.
 Phenoldisazorthotoluene, 557.
 Phenolorthosulphonic acid, orthopara-dichloro-, action of sulphuric acid on, *Proc.*, 1891, 64.
 Phenolphthalein, addition of, to mar-garin, 872.
 — anhydride, 1029.
 Phenols, action of alkali hydrosulphides on, 46.
 — action of epichlorhydrin on, 1198.
 — action of formaldehyde on, 1199.
 — action of hydrazine hydrate on, 1360.
 — action of phthalic chloride on, 1485.
 — action of thionyl chloride on, 186.
 — amido-, action of picric chloride on, *TRANS.*, 718.
 — condensation of benzaldehyde with, 1234.
 — condensation of unsaturated hydro-carbons with, 208, 571.
 — desmotropy in, 75.
 — nitro-, physiological action of, 1281.
 — quantitative reduction experi-ments on, 431.
 — sulphonation of, *Proc.*, 1891, 65.
 — thio-, preparation of, 1350.
 Pheno-2-methylmetadiazine, 745.
 Phenoxyacetal, 541.
 Phenoxyacrylic acids, optically active, 1482.
 Phenoxybutyramide, sulpho- γ -, 1468.
 Phenoxybutyric acid, γ -, 1468.
 Phenoxybutyronitrile, γ -, 1468.
 Phenoxyethylamine, 552.
 Phenoxypropylamine, γ -, 1467.
 Phenoxypropylaniline, γ -, 1467.
 Phenoxypropylphthalamic acid, γ -, 1467.
 Phenoxypropylphthalimide, γ -, 1467.
 Phenylacetic acid, *TRANS.*, 190.
 — constitution of, *TRANS.*, 194.
 — relationship with Paal's phenylmethylfurfurancarboxylic acid, *TRANS.*, 190.
 Phenyl acetal, thio-, 540.
 — acetylsalicylate and its nitro-de-rivatives, 915.
 — benzenesulphonate, 568.
 — bisazobenzenesalicylate, 1036.
 — biänyl ketone, 551.
 — α -chlorhydrin ether, 1198.
 Phenyl diphenylcarbamates, nitro- and amido-, 1215.
 — ether, molecular refraction and dispersion of, in solution, *TRANS.*, 591.
 — glycidyl ether, 1198.
 — hydroxyisophthalate, 1369.
 — methylphenylcarbamate, 1214.
 — methylphenylcarbamates, amido-, 1215.
 — — nitro-, 1214.
 — phenylsemithiocarbazide, para-chloro-, *TRANS.*, 212.
 — salicylate, derivatives of, 915.
 — — nitro-, derivatives of, 915.
 — sulphide, chloro-, 715.
 Phenylacetamide, nitro- and amido-, de-rivatives of, 562.
 Phenylacetone, thio-, 541.
 Phenylacetonedithethylmercaptole, thio-, 568.
 Phenylacetonediphenylmercaptole, thio-, 568, 1067.
 Phenylacetoneitrile, action of, on organic acids, 409.
 Phenylacetylhydrazine, 59.
 Phenylacetylhydroureacil, 197.
 Phenylacetylparatoluidide, 59.
 Phenylacetyltoluylenediamine, 694.
 Phenylallylsulphone, 1067.
 Phenylamido- α -naphthalazine, α -, 471.
 Phenylamidotoluyllamine, diamido-, 300.
 — dinitro-, 300.
 Phenylangelic acid, preparation of, 1225.
 Phenylazimidochlorobenzene, 300.
 Phenylazimidotoluyllamine, dinitro-, 300.
 Phenylazobenzene, dinitrosonitro-, 689.
 — orthonitrosocallometachlorodi-bromo-, 1861.
 Phenylazonaphthalenes, dinitronitroso-, 572.
 — dinitrosonitro-, 572.
 — orthoparadinitro-, 572.
 — orthoparadinitroso-, 573.
 — orthoparanitronitroso-, 573.
 Phenylazo- α -naphthol, action of diazo-sulphamic acid on, 1076.
 — action of metadiazobenzoic acid on, 1076.
 Phenylazo- α -naphtholmetacarboxylic acid, ortho-, 1074.
 — — para-, 1075.
 Phenylazoparaacetosol, 213.
 Phenylazoquinoline, α -, 1509.
 Phenylazorthocresosol, 212.
 Phenylazosalicylic acid, 1038.
 Phenylazotetrahydro- α -naphthaquinol-ine, 1259.
 Phenylbenzylinitrosamine, paranitroso-, 1206.

- Phenylbenzylloxycarbamide, 559.
 Phenylbenzyloxythiocarbamide, 558.
 Phenylbromacetic acid, an apparent exception to the Le Bel-Van't Hoff hypothesis, *TRANS.*, 71.
 Phenylbrouolactic acids, optically active, 1482.
 Phenylcarbamide, diparachloro-, *TRANS.*, 212.
 Phenylcarbazacridine, 219.
 Phenylchrysythiocarbamide, 731.
 Phenylcinnamic acid, orthonitro-, 214.
 Phenylconiine, orthoparadinitro-, 1245.
 Phenyldehydropentone, *TRANS.*, 886.
 Phenyl dianethoilmethane, metanitro-, 1347.
 Phenyl diazothiazole hydrate, 745.
 Phenyl-1': 3'-dihydrindazole, 2'-, 724.
 Phenyl dihydro- β -naphthatriazine, 840.
 Phenyl dinitroparachlorazobenzene, dinitronitroso-, 906.
 Phenyl diorcinolmethane, metanitro-, 1378.
 Phenyl diphenylsulphonepropane, thio-, 568.
 Phenyl diphoroglucinolmethane, metanitro-, 1378.
 Phenyl dipiperidyl, orthoparadinitro-, 1245.
 ——— paranitro-, 1245.
 Phenyl diresorcinolmethane, metanitro-, 1346.
 Phenyl disazo- α -naphthol, 1076.
 Phenyl ditetrahydroquinaldylmethane, amido-, 1102.
 Phenyl dithymolmethane, 1235.
 Phenyl enediamine, meta-, condensation of, with cinnamaldehyde, 1108.
 Phenyl enediamine dibenzylidenesulphonic acid, para-, sodium salt of, 721.
 Phenyl enedimethylaminediethylmethylphosphonium iodide, para-, 436.
 Phenyl enedimethylaminediethylphenylmethylphosphonium iodide, para-, 436.
 Phenyl enedimethylaminediethylphosphine, para-, 436.
 ——— oxide, para-, 436.
 ——— sulphide, para-, 436.
 Phenyl enedimethylaminediethylphosphine, para-, 435.
 ——— oxide, para-, 435.
 ——— sulphide, para-, 435.
 Phenyl enedimethylaminediphenylphosphine oxide, para-, 436.
 ——— sulphide, para-, 436.
 Phenyl enedimethylaminephenylmethylphosphine oxide, 436.
 Phenyl enedimethylaminetriethylphosphonium iodide, 436.
 Phenyl enedimethylaminetrimethylphosphonium iodide, para-, 435.
 Phenylethoxythiocarbamide, 558.
 Phenylethyl hydroxysophthalate, 1369.
 Phenylethylene glycol, parabromo-, 898.
 Phenylethylmethylamidopyrazole, 52.
 Phenylethylpropionic acid, preparation and properties of, 914.
 Phenyl- μ -ethylthiazole, α -, 221.
 Phenylfenchylamine, 1088.
 Phenylglycerol, 1198.
 Phenylglycoccine, synthesis of indigo with, 75, 206, 311, 456, 928.
 Phenylglycoccineparacarboxylic acid, 39.
 Phenylglyoxime peroxide, 316.
 Phenylglyoxyl, tetrathio-, 186.
 Phenylglyoxylic hydrazone, orthonitro-, isomeric form of, 302.
 Phenylhydrazidoacetic acid, asymmetrical, 1054.
 Phenylhydrazidophenylacetic acid, 438.
 Phenylhydrazine, action of carbonyl sulphide, carbonyl chloride, and alkyl chlorocarbonates on, 1212.
 ——— allocinnamate, 833.
 ——— cinnamaldehydrazonesulphonate, 1052.
 ——— cinnamate, 833.
 ——— hydrochloride, orthochloro-, *TRANS.*, 209.
 ——— hydrocinnamate, 833.
 ——— orthochloro-, 1043, *TRANS.*, 209.
 ——— parabanate, parachloro-, *TRANS.*, 213.
 ——— parachloro-, *TRANS.*, 211.
 ——— ——— action of chloroform and alcoholic potash on, *TRANS.*, 213.
 ——— thio-, 801.
 Phenylhydrazinebenzylidenesulphonic acid, sodium salt of, 720.
 Phenylhydrazine derivatives, action of, on the blood, 602.
 Phenylhydrazinephenylsemithiocarbamide, 1212.
 Phenylhydrazinepyruvic acid, orthochloro-, *TRANS.*, 210.
 Phenylhydrazines, chlorinated, *TRANS.*, 209.
 Phenylhydrazo-orthocresetol, 212.
 Phenylhydrazoparaeresetol, 218.
 Phenylhydrazoquinoline, α -, 1509.
 Phenylhydrocarbazacridine, 220.
 Phenylhydrocarbostyryl, 214.
 Phenylhydrocoumarin, 1484.
 Phenylhydrouracil, 197.
 Phenylhydroxyacetonitrile, imido-ethers of, 62.
 Phenylhydroxycarbamide, 1222.
 Phenylhydroxychlorothiazole, 745.
 Phenyl-2'-hydroxydihydroquinazoline, 8'-, 944.
 Phenylhydroxyhydrocoumarin, 1484.
 Phenylhydroxythiocarbamide, 558.
 ——— properties of, 1222.

- Phenylimidomethylpropionylacetonitrile, 52.
 Phenylimidothiazoline, μ -, 1517.
 Phenylindazole, 2', 723.
 ——— parachloro-, 724.
 Phenylindazolecarboxylic acid, nitro-, action of stannous chloride on, 1231.
 Phenylinduline, 1046.
 ——— amido-, 1046.
 Phenylisocrotonic acid, 2:4-dichloro-, 450.
 ——— 2:5-dichloro-, 451.
 ——— 3:4-dichloro-, 451.
 ——— parachloro-, 449.
 Phenylisophthalic acid, 1065.
 Phenylisoxalone, isonitroso-, 468.
 Phenylisoxazole, 451.
 Phenylisoxazolone, 469, 740, TRANS., 1005.
 Phenylketohydroxydimethylanilidotetrahydropyridinecarboxylic lactone, real nature of, 741.
 Phenyl-2'-ketotetrahydroquinazoline, 3', 944.
 Phenyl- β -lactaldehyde, orthonitrometachloro-, 1100.
 Phenyl- β -lactic acids, orthonitrometachloro-, 1099, 1100.
 Phenylactic ketone, orthonitrometachloro-, 1098.
 ——— methyl ketone, nitrochloro-, 1099.
 Phenyl- β -lacturamic acid, 197.
 Phenylmercaptomethylmercaptan, amido-, 1048.
 Phenyl-*ald*-metanitrophenylnaphthotriazine, *as*-, TRANS., 700.
 ——— metanitro-, TRANS., 693.
 Phenylmetatolulylpropane, $\alpha\beta$ -, 207.
 Phenylmethoxythiocarbamide, 558.
 Phenylmethylacrylic acid, nitration of, in the side chain, 1483.
 Phenylmethylfurfurancarboxylic acid of Paal, relationship of, to phenuvic acid, TRANS., 190.
 Phenylmethylhydroxypyrimidine, 468.
 Phenyl-*ald*-methylnaphthotriazine, *as*-paranitro-, TRANS., 697.
 ——— reduction of, TRANS., 712.
 Phenyl- α -methylpiperidine, orthoparadinitro-, 1245.
 Phenylmethylpyrazolone, action of sulphur dichloride on, TRANS., 334.
 ——— thio-, TRANS., 332.
 ——— properties of, TRANS., 335.
 Phenylmethylpyrazoloneazobenzene, TRANS., 336.
 Phenylmethyltriazolecarboxylic acid, oxidation of, 472.
 Phenyl- β -naphthol, diamido-, 301.
 ——— dinitro-, 300.
 Phenyl- β -naphthyl sulphides, 77.
 Phenyl- β -naphthylamine, dinitro-, 300.
 Phenyl-naphthylcarbazole, boiling point of, 1240.
 Phenyl-naphthylhydrazines, orthoparadinitro-, 572.
 Phenyl-nitroethylene, preparation of, 1483.
 Phenyl-nitroparachlorazobenzene, 2:4-dinitro-, 906.
 Phenyl-nitrosoimidothiazoline, 745, 1517.
 Phenylortho-chlorazobenzene, dinitro-nitroso-, 1048.
 Phenylortho-naphthalenediamine, condensation of, with benzoin, 748.
 Phenylorthophenylene-guanidine, 1469.
 Phenylorthotolulylpropane, $\alpha\beta$ -, 207.
 Phenylsotriazaldehyde, *n*-, 1113.
 Phenylsotriazole, *n*-, 1113.
 ——— homologues of, 1115.
 Phenylsotriazolecarboxylamide, *n*-, 1113.
 Phenylsotriazolecarboxylic acid, *n*-, 1112.

- and ethyl succinosuccinate, relationship between, 1485.
- benzenesulphonate of, 569.
- detection of dirosorcinol in synthetically prepared, 125.
- formation of, in plants, 605.
- Phosphan, action of methyl or ethyl alcohol on, 1008.
- Phosphamide, fluoro-, 1418.
- Phosphates, alcohol method of estimating iron and aluminium oxides in, 1138.
- estimation of ferric oxide and alumina in, 114, 245, 501, 963.
- magnetic rotation of, *Proc.*, 1890, 144.
- metallic, electrolysis of, in acid solution, 1140.
- Phosphatic manures, estimation of ferric oxide and alumina in, 245.
- Phosphine, action of phosphorous chloride on, 398.
- preparation of, 397.
- Phosphodichloromuconic acid, TRANS., 27.
- Phosphodichloromuconyl chloride, TRANS., 31.
- Phosphododecatungstic acid, 1159.
- Phosphorescence of lithium compounds in vacuo, 249.
- of minerals under the influence of light and heat, 776.
- Phosphoric acid, economy of, in the growth of beetroot, 612.
- estimation of, in rock analysis, 768.
- estimation of, in urine, 619.
- pure, preparation of, 398.
- soluble, in superphosphates, Belgian method of estimating, 1289.
- the citrate method of estimating, 248.
- total, estimation of, in manures, 1397.
- anhydride, action of phosphoryl chloride on, TRANS., 202.

- Phosphorous acid, estimation of, 243.
 — anhydride, action of sulphuric anhydride on, TRANS., 230.
 — diamide, TRANS., 1027.
 — oxide, TRANS., 1019.
 — action of ammonia on, TRANS., 1026.
 — action of bromine on, TRANS., 1020.
 — action of hydrogen chloride on, TRANS., 1022.
 — action of iodine on, TRANS., 1021.
 — action of light on, TRANS., 1019.
 — action of nitric peroxide on, TRANS., 1028.
 — action of phosphorus trichloride on, TRANS., 1029.
 — action of phosphorus pentachloride on, TRANS., 1028.
 — action of selenium on, TRANS., 1026.
 — action of sulphur on, TRANS., 1022.
 — action of sulphur chloride on, TRANS., 1026.
 — action of sulphuric acid on, TRANS., 1026.
 Phosphorus, a new modification of, PROC., 1891, 3.
 — action of, on sulphuric anhydride, TRANS., 231.
 — bromides, combination of ammonia with, 398.
 — chlorides, combination of ammonia with, 398.
 — estimation of, in pig-iron, steel, and iron ore, 863.
 — in iron, densimetric estimation of, 961.
 — molecular weight of, in solution, 260.
 — oxides, compounds of, with sulphuric anhydride, TRANS., 230.
 — oxyfluoride, 264.
 — pentafluoride, action of, on heated spongy platinum, 1438.
 — sulphoxide, TRANS., 1023.
 — trichloride, action of, on organic acids and water, 170.
 — trifluoride, 264.
 — trifluorodichloride, 1417.
 Phosphoryl chloride, action of, on phosphoric anhydride, TRANS., 202.
 Photoanethoil, 1347.
 Photographic method, new, 138.
 — plates, borax in developers for, 139.
 — sensitizers for rays of low refrangibility, 1145.
 Phthalaldehydic acid, 1369.
 Phthalaldehydic acid, action of potassium cyanide on, 1225.
 Phthalamide, compounds of, with phenols, 65.
 Phthaleins, 1029.
 Phthalic acid, 5-bromo-4-chloro-, 921.
 — 4 : 5-dichloro-, 921.
 — anhydride, 4 : 5-dichloro-, 921.
 — chloride, action of, on phenols, 1485.
 Phthalicsulphinide, derivatives of, 1063.
 Phthalidylhydrazobenzene, 1870.
 Phthalimide, action of hypobromites on, 1217.
 — isomeride of, 1218.
 Phthalimidopropylmercaptan, β -, 1473.
 Phthalodiamide, action of hypochlorites and hypobromites on, 1216.
 Phthalylidextroecogonine, ortho-, 476.
 Phthalyltaurine, 816.
 Physics and chemistry, energy content in, 1414.
 Physiological action and chemical constitution, 1279.
 — of amides, 1282.
 — of anilides, 1282.
 — of antipyretics, 602.
 — of benzene and its derivatives, 1279.
 — of cocaine, 486.
 — of curare, 487.
 — of definitely related chemical compounds, 1393.
 — of guaiacol, 99.
 — of hydrazine, 239.
 — of hydrazines, 1280.
 — of lupetidine and allied substances in relation to their chemical constitution, 854.
 — of nickel carbon oxide, 1130.
 — of nitrobenzenes, 1280, 1281.
 — of nitrophenols, 1281.
 — of ozone, 1531.
 — of potassium ferrocyanide, 99.
 — of pyridine, quinoline, &c., 602.
 — of saline solutions and various drugs, 601.
 — of saponins, 1531.
 — of soluble strontium salts, 99.
 — of strychnine, 486.
 — of thebaine, narcotine, and their derivatives, 762.
 Piaselenole, constitution of, 394.
 Picene, boiling point of, 1240.
 Pickeringite from Tarapaca, 1436.
 Picoline, α -, 81.
 Picoline, β -, 325, 1092.
 Picolinebetaine, β -, and its salts, 942.
 Picolinetricarboxylic acid, 1096.

- Picolinic acid, action of sodium amalgam on, 734.
 Picolyalkine, α -, derivatives of, 1092.
 Picramidophenol, ortho- and para-, 719.
 Picric chloride, action of, on amines in presence of alkali, TRANS., 714.
 Picroacnitive, TRANS., 272.
 Picropharmacolite from Missouri, 275.
 Picropodophyllie acid, 1134.
 Picropodophyllin, 1134.
 Picroseptdecylamine, TRANS., 715.
 Picrylazonaphthalenes, 572.
 Picrylnaphthylhydrazines, 571.
 Picrylnitroparachlorazobenzene, 906.
 Picrylorthochlorophenylhydrazine, 1043.
 Picrylparabromophenylhydrazine, 1361.
 Picrylparachlorazobenzene, 905.
 Picrylparachlorophenylhydrazine, 905.
 Pigment, cutaneous, as an antecedent of hæmoglobin, 480.
 Pimelic acid, isomeric, from amylen bromide, 1017.
 ——— preparation of, TRANS., 825.
 ——— synthesis of homologues of, TRANS., 818.
 ——— acids, 289.
 Pinakiolite from Sweden, 404.
 Pine tree honey-dew and honey, 412.
 Pinene, 1081.
 ——— constitution of, 1242.
 ——— dibromide, 1241.
 Pinenephthalamic acid, 1086.
 Pinenephthalimide, 1086.
 Pinole and its derivatives, oxidation of, 218.
 ——— glycol, 217.
 ——— diacetate, 217.
 ——— hydrate, 218.
 ——— tribromide, 218.
Pinus khasyana, turpentine oil from, TRANS., 311.
 Pipicolinic acid, preparation of, 735.
 Pipocolylalkine, α -, derivatives of, 1093.
 Piperazudin, identity of, with diethylenediamine, 169.
 Piperazine, 415, 416, 735.
 ——— identity of, with diethylenediamine, 169.
 ——— nitroso-, 1883.
 ——— non-identity of spermine with, 538.
 Piperidine, action of, on calcium chloride, 377.
 ——— action of picric chloride on, TRANS., 716.
 ——— benzyl derivatives of, 88.
 ——— derivatives of, 1244.
 ——— introduction of bivalent radicles into, 1246.
 Piperidine-bases, behaviour of, towards aromatic halogen compounds, 1245.
 ——— synthesis of, 1092.
 Piperidinecarboxylic acids, 735.
 Piperidinedibromisatin, 1491.
 Piperidyl-1-thiocarbamilide, 1245.
 Piperonal, bromo-, derivatives of, 1474.
 ——— derivatives, 704.
 Piperonalloxime, bromo-, 1475.
 ——— orthamido-, 706.
 Piperonalphenylhydrazone, orthonitro-, 706.
 Piperonyl, some derivatives of, TRANS., 150.
 Piperonylacryl methyl ketone, 705.
 ——— bromo-, 1475.
 ——— orthonitro-, 705.
 Piperonylacrylic acid, TRANS., 152.
 ——— action of nitric acid on, TRANS., 153.
 ——— amido-, TRANS., 158.
 ——— nitro-, TRANS., 153.
 ——— from nitropiperonal, TRANS., 157.
 ——— salts of, TRANS., 154.
 ——— tetrabromo-, TRANS., 160.
 ——— action of potassium hydroxide on, TRANS., 160.
 ——— α - and β -tribromo-, TRANS., 163.
 Piperonylethylene, tribromo-, TRANS., 161.
 Piperonyllactyl methyl ketone, bromo-, 1476.
 Piperonylnitrile, 711.
 ——— orthonitro-, 706.
 Piperonyloin, TRANS., 164.
 Piperylbiguanide, 735.
 Piperylbiguanidine, 839.
 Piperylthiosinamine, 549.
 Piperylpseudothiosinamine, 549.
Pisum sativum, composition of the seeds of, 1542.
 ——— constituents of the seed pods of, 606.
 ——— nitrogen assimilation by, 1533, 1536.
 Pitch, brewer's, examination of, 512.
Pithecolobium bigeminum, alkaloid from, 336.
 Pitticite from Utah, 275.
 Plant, action of diastase on starch grains within the, 605.
 ——— cells, chemical composition of the membrane of, 1178.
 ——— nutrition, substitution of manganese for iron in, 1394.
 Plants, acquisition of atmospheric nitrogen by, 353, 491.
 ——— assimilation of nitrogen by, 855.
 ——— behaviour of tannin in, 104.
 ——— calcium and magnesium oxalates in, 857.
 ——— detection of tannin in, 770.

- Plants, direct absorption of ammonia compounds by, 1545.
 — effect of copper compounds on, 401.
 — estimation of citric acid in, 129.
 — formation of closed carbon chains in, 655.
 — formation of phloroglucinol in, 605.
 — green, assimilation of mineral salts by, 604.
 — presence and function of diastase in, 856.
 — presence and function of sulphur in, 606.
 — value of nitrates and ammonium salts as food for, 1135.
 Plaster casts, hardening of, 1421.
 Platinic chloride and its compounds, thermochemistry of, 966.
 — compounds of, with hydrogen chloride, 1325.
 — hydroxide, action of, on tungstates, 1323.
 Platinum, action of chlorine and carbonic oxide on, *TRANS.*, 598.
 — action of nitrosyl chloride on, *TRANS.*, 663.
 — bromonitro-compounds of, 807.
 — dibromide, action of carbonic oxide on, *TRANS.*, 603.
 — electrical resistance of, 5.
 — electrolytic estimation of, 1140.
 — electrolytic separation of cadmium, gold, silver, and of mercury from, 1396.
 — electrolytic separation of silver from, 1296.
 — phosphorus fluoride, 1433.
 — spongy, very sensitive, 1321.
 — thiocarbide, 19.
 Platinum-compounds, volatile, *TRANS.*, 598.
 Platinum-group, detection and estimation of the metals of, in the presence of other metals, 1554.
 Platinum-metals, atomic weights of, 885.
 Plumbiferite from Sweden, 1435.
 Plumbonacrite, 275.
 Plums, sugar from the pectin of, 413.
Pneumococcus of Friedländer, fermentations induced by, *TRANS.*, 253.
 Podophyllic acid, 1134.
 Podophylloquercetin, 1134.
 Podophyllotoxin, 1133.
 Poisoning by aniline, chlorates, and mercuric chloride, 853.
 — by hydrocyanic acid applied to the surface of the eye, 99.
 — detection of conine in a case of, 871.
 Poisons, action of, on nerve fibres and peripheral nerve cells, 485.
 Poisons, organic and inorganic, detection and estimation of, in corpses, 117.
 Polarisation, circular, of certain tartrate solutions, 249.
 — electromotive forces of, 1405.
 Polesi, oil of, 934.
 Polluto from Hebron, Maine, 993.
 Polycarboxylic fatty acids, synthesis of, 546.
 Polycrase of North and South Carolina, 1329.
 Polymerism in mineral chemistry, 258.
 Polypes of the nose, analyses of, 832.
 Potash, apparatus, new, for elementary analysis, 621.
 Potassium and sodium sulphates, supposed isomorphism of, 147.
 — bromide as indicator in chlorimetry, 615.
 — carbonylthiocyanoplatinite, 1165.
 — chlorate, influence of potassium salts on the solubility of, 1319.
 — cholesteroxide, 299.
 — cobalt oxalate, 1189.
 — cyanide, oxidation of, with potassium permanganate, 160.
 — ferricyanide, reactions of, 410.
 — ferrocyanide, physiological action of, 99.
 — hydrogen succinate, dry distillation of, 1012.
 — tartrate, 676.
 — estimation of, in wine, 371.
 — influence of inorganic potassium salts on the solubility of, 974.
 — iodate as original standard for iodometry, acidimetry, and alkali-metry, 614.
 — isopropylsulphonate, 180.
 — lead-copper nitrite, 1157.
 — manganate, decomposition of, by ammonium salts, 1159.
 — mercuric sulphates, 879.
 — myronate, 818.
 — nitrite, preparation of, 1321.
 — osmiate, preparation of, 1433.
 — permolybdate, 988.
 — persulphate, 982, *TRANS.*, 772.
 — phlojonate, 465.
 — platibromonitrite, 808.
 — propionate, thermochemistry of, 1313.
 — rhodium nitrite, 808.
 — salts, magnetic rotation of, *PROC.*, 1890, 142.
 — molecular refraction and dispersion of, in solution, *TRANS.*, 595, 596.
 — silicozirconate, 1431.
 — spectrum of, 137.

- Potassium stannichloride, hydrate of, 1160.
 — sulphate, influence of potassium halides on the solubility of, 974.
 — tungstovanadates, 18.
 Potato spirit liquor, examination of, 105.
 — sprouts, solanidine of, 473.
 Potential, contact, difference of, of metals, 189.
 Powellite, 886.
 Precipitates, change of, from the amorphous to the crystalline form, 875.
 Precipitation, 874.
 Pressure, effect of, on the electrical conductivity of liquids, 250.
 — influence of, on dissociation, 381.
 — of compressed gases, 520.
 — osmotic law of, 522.
 — variations of certain high temperature boiling points, 9.
 Pressures, critical, determination of, 779.
 Primuline, photographic printing of, 139.
 Primuline-group, dyes of the, 195.
 Propaldehyde, action of, on alcohols, 284.
 — β -bromo-, 37.
 Propane, nitro-, primary, action of alkalis on, TRANS., 431.
 Propanetetracarboxylic acid, 424.
 Propenylbenzene and allylbenzene derivatives, discrimination between, 551.
 Propenyldiphenylureide, 60.
 Propenyltricarboxylic acid, action of bromine on, 202.
 Propionamide, thio-, 220.
 Propionic acid, β -bromo-, 37.
 — — β -nitroso-, 1458.
 — — thermochemistry of, 1313.
 Propionitrile, action of, on organic acids, 400.
 — molecular refraction and dispersion of, TRANS., 296.
 Propionoguanimine, 416.
 Propionylbenzoyl ethyl cyanide, imido-, 889.
 Propionyl dinitrophenol, 447.
 Propionylethyl cyanide, oximido-, 889.
 Propionyl- α -naphthol, 447.
 — hydrazone, 448.
 Propionyl- α -naphtholazobenzene, 448.
 Propionylphenol, 447.
 — hydrazone, 447.
 Propionylquinol, 447.
 — hydrazone, 447.
 Propionylresorcinol, 447.
 — hydrazone, 447.
 Propyl, change of, into isopropyl in the cumene series, 45.
 — phenyl ether, γ -bromo-, 1467.
 Propyl, α -pyridyl ketone, and its derivatives, 1505.
 — — pinacone of, 1505.
 — β -pyridyl ketone and its derivatives, 1506.
 — sulphide, occurrence of, in Ohio petroleum, 1172.
 Propylamine hydrochloride, diseleno-, 1216.
 — molecular refraction and dispersion of, TRANS., 296.
 — seleno- and thio-derivatives of, 1216.
 Propylbenzene, parabromo- $\alpha\beta$ -dibromo-, 898.
 — synthesis of, 685.
 Propylbenzoic acids, bromopara-, 1023.
 Propylcyanocamphor, 1409.
 Propyldimethylsuccinic acid, 829.
 Propylene diethyl sulphide, 181.
 — diphenyl sulphide, 181.
 — oxide, heat of combustion of, 683.
 Propylenediphenylsulphone, 181.
 Propyl-group in cymene, nature of, 686.
 Propylhomopiperidinic acid, α -, 467.
 Propylidene diethyl ether, 284.
 — dimethyl ether, 285.
 Propylideneacetic acid, 1453.
 — — from malonic acid and from orthamidophenol, 821.
 Propylisopropylbenzene, para-, and its derivatives, 1023.
 Propylisopropylbenzenes, synthesis of, 686.
 Propylisopropylbenzenesulphonic acid, para- 686.
 — acids, 1024.
 Propylisopropylnitramine, 168.
 Propylnitramine and its derivatives, 167.
 Propylparatoluidine, TRANS., 35.
 — normal and iso-, TRANS., 33.
 Propylparatolynitrosamine, TRANS., 35.
 Propylphthalimide, β -bromo-, 1472.
 Propylpiperidone, β -, 468, 1246.
 Propylpseudothiosinamine, 549.
 Propylpyridylalkine, α -, 1505.
 Propyl- γ -selenidophthalamic acid, 1216.
 Propylthiosinamine, 549.
 Propyltoluene, para-, synthesis of, 1022.
 Propyltricarballic acid, 546.
 Proteid absorption, 233.
 — in normal urine, 1130.
 — influence of, on the digestion of foods free from nitrogen, 344.
 — from gedda gum, TRANS., 1061.
 — metabolism, influence of alcohol on, 1272.
 — — influence of carbohydrates on, 846.
 — — influence of muscular work on, 479.

- Proteid metabolism, influence of sulphonal on, 1523.
 — requirement of healthy men, 1272.
 Proteids, a product of the putrefaction of, 948.
 — action of alcohols and aldehydes on, 947.
 — action of salts on the coagulation of, by heat, 954.
 — decomposition products of, 590.
 — effect of certain organic acids on the digestion of, 751.
 — estimation of, 1302, 1304.
 — formation of nitrogenous organic bases by the decomposition of, in the vegetable organism, 856.
 — heat-coagulation of, 1521.
 — in food rations of grown animals, effect of an increase in, 753.
 — influence of oil or fat on the digestibility of, 752.
 — new test for, 872.
 — of milk, 339, 951.
 — of the blood, relation of dextrose to the, 350.
 — of the oat-kernel, 1285, 1390.
 — pathology of, 761.
 — synthesis of, 588.
 Protoses, conversion of, into peptones, 953.
 Protogelatinose, 950.
 Protoglucose, 232.
 Protomyosinose, 950.
 Protonontronite, 650.
 Protopine, 229, 844.
 Protoplasm, toxic action of quinine on, 1531.
 Protoveratridine, 231.
 Protoveratrine, 230.
 Protovitellose, 343.
 Proustite and pyrrargyrite, 273.
 Pseudephedrine, constitution of, 1264.
Pseudochrocia glomerata, alkaloid from, 336.
 Pseudocodeine, 1121.
 Pseudoconhydrine, 1119.
 — formation of, from ethyl α -pyridyl ketone, 1505.
 Pseudocumene, hexahydro-, 185.
 Pseudocumenezaphenol, 1210.
 Pseudocumeneinnamene, 207.
 Pseudocumidine, commercial, 1351.
 — nitration of, 693.
 Pseudocumylglyoxylic acid, 1225.
 Pseudo-haemoglobin, 845.
 Pseudojervine, 58.
 Pseudolutidostyrylcarboxylic acid, 676.
 Pseudolutidostyryldicarboxylic acid, 676.
 Pseudonitropurpurin, 1073.
 Pseudopeptone, 235.
 Pseudophenylhydrazidomandelic acid, nitroso-, 430.
 Pseudotropine, 1265.
 — oxidation of, 1520.
 Ptomanes, 845.
 — formed in the cultivation of the bacillus of swine fever, 476.
 — formed in the decomposition of conglutin, 590.
 — influence of oxygen on the formation of, 1267.
 Pulegonamine and its derivatives, 936.
 Pulegone, 936.
 — action of hydrogen bromide on, 937.
 Pulegoneoxime, 936.
 Pump, sprengel, automatic, 875.
 — modification of, 524.
 Purpurin, amido-, 1078.
 — nitro-, 1078.
 Pus, blenorrhagic, toxalbumin secreted by the microbe of, 1521.
Pygium parviflorum and *P. latifolium*, amygdalin in, 338.
 Pyramilpyromlactone and citraconanil, identity of, 73.
 Pyrrargyrite and proustite, 273.
 Pyrazole, derivatives of, 1106.
 Pyrazoledicarboxylic acids, β -, 330.
 Pyridine, benzyl derivatives of, 88.
 — carbonyl bromoplatinite hydrobromide, 1164.
 — chlorhydrin, 1388.
 — compounds of, with metallic salts 732, 838.
 — Hantzsch's synthesis, 1090.
 — β -ketone, derivatives of, 1505.
 — physiological action of, 602.
 Pyridine-bases, betaines of, 941.
 — hydrated, oxidation of, 722.
 — of the β -series, synthetical, 579.
 Pyridinebetaine salts, 941.
 Pyridinebetaines, 1388.
 Pyridinecarboxylic acids, non-nitrogenous acids derived from, 733.
 Pyridine-derivatives, synthesis of, from derivatives of α -pyrone, 939.
 Pyridinedicarboxylic acid, bromo-, 580.
 Pyridinetricarboxylic acid, 1097.
 Pyridyl ketones, 1503.
 Pyrites, estimation of sulphur in, 496.
 Pyrites-burner-gases, testing, 496.
 Pyrocinchonic anhydride, preparation of, 1456.
 Pyrogallol, action of aldehyde on, 48.
 — benzenesulphonate of, 569.
 Pyrolusite, valuation of, by means of hydrogen peroxide, 245.
 Pyromucic acid, 295.
 — preparation of, 676.
 — preparation of, from furfur-aldehyde, 896.

- Pyrone, 1195.
 — constitution of, 1196.
 — synthesis of, 1333.
 Pyrone, α -, derivatives of, synthesis of pyridine derivatives from, 939.
 Pyropentylene, 1085.
 Pyrroline, action of methyl alcohol on, 1501.
 — constitution of, 1090.
 Pyrrolines, action of hydroxylamine on, 1502.
 Pyruvic acid hydrazone, 1333.

Q.

- Quartz, pseudomorphous, after stibnite, 155.
 Quercetin and its derivatives, 1386.
 Querlactone, 1062.
 Quinaldine, condensation of metanitrobenzaldehyde with, 329.
 — synthesis of, 1101.
 Quinaldinesulphonic acid, β -, constitution of, 329.
 Quinaldinic acid, oxidation of, 1096.
 — preparation of, 1096.
 Quinalizarin and its derivatives, 935.
 — formation of, from alizarin, 463.
 Quinazolines, 943.
 Quinethyline, and its derivatives, 1513.
 Quinic acid, constitution of, 921.
 Quinindole- α -carboxylic acid, ortho-, TRANS-, 758.
 Quinine, action of hydriodic acid on, 1517.
 — as a protoplasmic poison, 1531.
 — bark, estimation of the total alkaloids in, 1402.
 — conversion of cuprefine into, 1121.
 — estimation of, 134.
 — mucate, TRANS-, 754.
 — sulphate, analysis of, 964.
 — assay of, by the ammonia process, 772.
 — fractional crystallisation of, 964.
 Quinol benzenesulphonate of, 569.
 Quinoldiammonium, 1360.
 Quinoldisulphonic acid, dibromo-, 1029.
 Quinoline alkylidides, action of alkalis on derivatives of, 736.
 — amido-, preparation of, 1509.
 — 1 : 3 : 4'-bromo-, 82.
 — carbonylechloroplatinite hydrochloride, 1163.
 — 2 : 2'-dibromo-, 1248.
 — 3 : 2'-dibromo-, 1248.
 — 4 : 2'-dibromo-, 1249.
 — hydrazine, ortho-, TRANS-, 756.
 — oxidation of, 1095.
 — physiological action of, 602.

- Quinoline, sulphonation of, 391.
 — 1 : 3 : 4 : 4'-tetrabromo-, 83.
 — 1 : 4 : 4'-tribromo-, 83.
 Quinolinealkylammonium hydroxides, oxidation of, 736.
 Quinolinebenzocarboxylic acids, oxidation of, 1889.
 Quinoline-bases, formation of, 1509.
 Quinoline-derivatives, methiodides of, 1247.
 — oxidation of, 1094, 1389.
 Quinolinedioximeanhydride, 580.
 Quinolinedioximes, 580.
 Quinolines, bromo-, action of hypochlorous acid on, 1248.
 Quinolinesemicarbazide, ortho-, TRANS-, 758.
 Quinols, alkyl-, diphenyl derivatives from, 208.
 Quinolylacetaldehyde, 2', 83.
 Quinolylacetic acid, 2', 84.
 Quinolylacetylene, 2', 84.
 Quinolylidibromomethylene, 2', 84.
 Quinolylidibromopropionic acid, 2', 84.
 Quinolylidihydroxypropionic acid, 2', 84.
 Quinolylpropionic acid, 2', 84.
 Quinone, chlorobromo, meta- and para-, 1348.
 — constitution of, 432, 1348.
 — dichloride, 1348.
 — dichloride dibromide, 1348.
 — tetrabromo-, 1028.
 — tetrachloride, 1348.
 Quinonecarboxylic acids, 455.
 Quinones, alkyl-substituted, action of alkalis and amines on, 903.
 — orientation by conversion of para-dinitro-derivatives into, 1199.
 Quinoxaline from tetramidotoluene sulphate, 192.
 Quinoxalino-series, new class of fluorescent dyes of, 747, 1109, 1514.

R.

- Rabbits, aged, composition of the bones of, 1275.
 Raffinose, red sediment formed in a solution of, 813.
Rauwolfia (ophioxylon) serpentina, alkaloid from, 336.
 Reaction, velocity of, between metals and halogens, 1149.
 — in gelatin, 638.
 Reactions at high temperatures and pressures, 258.
 — chemical, dead space in, 1150.
 Reduction processes, 431.
 Reflectometer, total, 513.

- Refraction and chemical constitution of gases and vapours, 629.
 — estimation of the strength of solution by them, 1805.
 — in certain metals, 373.
 — influence of the change of volume on mixture of two liquids on, 2.
 — molecular, of substances containing nitrogen, 373.
 — of various carbon compounds, TRANS., 290.
 — of various substances in solution, TRANS., 589.
 — of fluorobenzene, 774.
 — of nickel carbon oxide, 1322.
- Refractive and rotatory powers of chemical compounds, relation between, 188.
 — energy, molecular, of some triethylsulphine derivatives, 1305.
 — of sulphur dichloride, 149.
 — index of pyrone, 1195.
 — indices, measurement of, at high temperatures, 513.
 — of liquids, instrument for comparing, 959.
 — of water, 629.
 — power of levulose and invert sugar, 1000.
 — of organic compounds at different temperatures, PROC., 1891, 115.
- Refractometer, difference, 1305.
- Rennet extract, action of, on casein, 1272.
- Resin, estimation of, in soap, 131.
 — from Thwaites's *Doona zeylanica*, 1385.
 — oil, detection of, in oil of turpentine, 870.
- Resorcinol, action of chloral on, 48.
 — action of chlorine on, 689.
 — condensation of metanitrobenzaldehyde with, 1346.
 — heptachloro-, 690.
 — pentachloro-, 689.
 — trichloro-, 689.
 — test for, 370.
- Resorcinolphthalimidesulphonic acid, 66.
- Resorcinyi benzenesulphonate, 569.
- Respiration, human, air being re-breathed, 1270.
 — see also Metabolism, gaseous.
- Respiratory changes, effect of acetic acid on, 344.
 — exchange in animals, 593.
 — exchange of gases, 1270.
- Retene, boiling point of, 1240.
- Rhamnitol, 31.
- Rhamnoctonic acid, 32.
 — lactone, 32.
- Rhamnoctose, 32.
- Rhamnoheptonic acid, 32.
 — hydrazide, 32.
- Rhamnoheptose, 32.
- Rhamnohexitol, 32.
- Rhamnohexonic acid, 31.
- Rhamnohexose, 31.
- Rhammonic acid, rotatory power of, 44.
- Rhamnose, estimation of, 1143.
- Rhamnoseoxime, 664.
- Rhinoliths, 1279.
- Rhizoma podophylli, constituents of, 1133.
- Rhodanic acid, constitution of, 943.
- Rhodium, atomic weight of, 616.
 — double nitrites of, 808.
 — electrolytic estimation of, 141.
 — salts, ammoniacal, 1325.
- Rhodizonic acid, constitution of, 189.
- Rhodochrosite from Franklin Furnace, New Jersey, 527.
- Rhodonite, Fowlerite variety of, from New Jersey, 530.
- Rhynchosia macrantha*, alkaloid from, 337.
- Rhyolites from Sweden, 1437.
- Rice, manuring experiments with, 1547.
- Rice meal, digestibility of, 595.
- Ricinoleic acid, polymerides of, 1454.
- "Ricotta" from sheep's milk, 952.
- Rings containing five atoms, constitution of, 1090.
- Robinia pseudacacia*, assimilation of nitrogen from the air by, 764.
 — nitrogen assimilation of, 1533, 1534.
- Rock analysis, separation of titanium, chromium, aluminium, iron, barium, and phosphoric acid in, 768.
- Rocks, eruptive, from the Cabo de Gata, 26.
 — from Corsica, 1440.
 — of the eruptive mass of Jablonica, 652.
 — spherulitic, from Co. Down, 1160.
- Root nodules of the pea, 607.
- Roseochromium hydrogen nitrate, 1327.
- Roseocobalt hydrogen nitrate, 1327.
- Roseorhodium hydrogen nitrate, 1327.
- Roses, oil of, 219.
 — detection of Turkish goranium essence in, 1555.
 — Gorman and Turkish, 323.
- Rosindone, 746.
 — bromo-, 1045.
- Rosindonic acid, 1045.
- Rosindulines, 1044.
- Rosindulone, 746.
- Rotatory and refractive powers of chemical compounds, relation between, 188.
 — dispersion of tartrates, 1145.

Rotatory power of compounds of mannitol with acid molybdates, 1443.
 — of gluconic, galactonic, and rhammonic acids, 43.
 — of grape sugar, influence of inactive substances on, 1174.
 — of turpentine, change of, on keeping, *TRANS.*, 726.
 — powers of camphols and isocamphols, influence of solvents on, 575.
 — of levulose and invert sugar, 1178.
 Rubeanic acid, 1008.
 "Rubcanwasserstoff," 1008.
 Rubidium barium dithionate, 802.
 — spectrum of, 137.
 Rubies, synthesis of, 156.
 Ruthenium nitrososchloride, ammoniacal derivatives of, 401.
 Rye bran, arabinose from, 33.

S.

Sabadilla seeds, alkaloids of, 844.
 — — fat and ethereal oil of, 1284.
 Sabadine, 844.
 Sabadinine, 841.
 Saccharic acid, reduction of, 677.
 — acids, d- and l-, configuration of, 1176, 1445.
Saccharomyces Hansenii, 857.
 Saccharose, inversion of, by hydrochloric acid, 535.
 Safranines, eurhodines, and indulidines, reactions between, 1213.
 Saffrole, molecular refraction and dispersion of, *TRANS.*, 295.
 Salicylaldehyde, isomeric modification of, 193.
 Salicylic acid, artificial, impurities in, 454.
 — — azo-dyes from, 1038.
 — — dichloro-, 711.
 — — nitration of, with nitrous acid, 307.
 Salicyldichlorhydrin, 708.
 Salicylmetahydrobenzoic acid, 50.
 Saligeninooxyacetic acid, 300.
 Saliva, human, diastatic action of, 1522.
 — influence of temperature on, 1272.
 Salol, derivatives of, 915.
 Salt, effect of, on digestion, 751.
 — solutions, aqueous, vapour pressures of, at 0°, 783.
 — — change of colour of, 1319.
 — — electrical conductivity of, 141.
 — — influence of water of crystallisation on the electrical conductivity of, 141.

Salts, conduction of electricity by the vapours of, 515.
 — cryohydrates of mixtures of, 388.
 — crystalline, hydrated, constant vapour pressure of, 781.
 — double and complex, 6.
 — — aqueous solutions of, 6.
 — — solutions of, 973.
 — electrical resistance of, in the Bunsen flame, 5.
 — formation of, *Proc.*, 1891, 118.
 — in solution, osmotic pressure of, *TRANS.*, 344.
 — magnetic rotation of solutions of, *Proc.*, 1890, 143.
 — mineral, estimation of, in wine, 371.
 — mixed, solubility of, in water, 795.
 Samarium, atomic weight of, 985.
 — oxide, 985.
Sanguinaria canadensis, alkaloids of the roots of, 843.
 Sanguinarine, 844.
 Sapogenol, 938.
 Saponification by means of sodium ethoxide, 1143.
 Saponin, 938.
 Saponine, reaction for, 1562.
 Saponins, 1531.
 — physiological action of, 1531.
 Sarcoma, melanotic, urine and blood in a case of, 484.
 Scapolite, conversion of a felspar into, 277.
 — from Pennsylvania, 155.
 Scheelite, proportion of molybdenum in, 406.
 Schreiner's base, 750.
Scopolia atropoides, root constituents of, 228.
 Seas, modern, silica and siliceous remains of organisms in, 905.
 Sebacic acid, dibromo-, 1191.
 Seeds, leguminous, chemical composition of some, 1541.
 — — nitrogenous bases in, 400.
 — of star-anise, composition of, 957.
 Selenic acid, molecular refraction and dispersion of, in solution, *TRANS.*, 593.
 Selenious acid, crystals of, 393.
 — — molecular refraction and dispersion of, in solution, *TRANS.*, 593.
 — — cyanide, 393.
 Selenites, 262.
 Selenium, 393.
 — and tellurium minerals from Honduras, 153.
 — cells, experiments with, 777.
 — chlorides, dissociation of, 11.
 — estimation of, 262.
 — sulphur and tellurium, isomorphism of, 1417.

- Selenodiethylaniline, 696.
 Selenodimethylaniline, 696.
 Selenophthalide, 1461.
 Selenophthalimidine, 1460.
 Selentellurium, 153.
 Seminose, 356.
 Senegine, reaction for, 1562.
 Sensitisers for rays of low refrangibility, 1145.
 Serpentine from Canada, 647.
 Sesame oil, detection of, in olive oil, 1400.
 Sheep, influence of wool on the material exchange in, 1392.
 — milk of the, 951.
 Shells, organic basis of, 236.
 Shikmic acid, 919.
 — dibromide, 920.
 Shikmolactone, bromo-, 920.
 Sideronatrite from Chili, 274.
 Sigterite, a new felspar from Sigterø, 22, 1438.
 Silica, action of magnesium on, 801.
 — and the siliceous remains of organisms in modern seas, 995.
 — estimation of, in presence of iron, 1397.
 Silicate containing copper and silver, 275.
 Silicates, amorphous, from Budapest, 1438.
 — ethereal, action of phosphorus oxychloride on, 814.
 — in soil, decomposition of, by lime and gypsum, 1135.
 — natural, constitution of, 529.
 — new method for decomposing, 619.
 — undetermined from the Kaiserstuhl, 650.
 Silicobromoform, 642.
 Silicon, action of magnesium on, 801.
 — bromiodides, 1419.
 — bromochlorides, 981.
 — chloride, action of hydrogen bromide on, 981.
 — — action of hydrogen iodide on, 800.
 — chloriodides, 1418.
 — chlorotriiodide, 801.
 — diiododichloride, 800.
 — electrolysis of fused compounds of, 1321.
 — ethoxychlorides, action of phosphorus oxychloride on, 1171.
 — iodochloride, 800.
 — new form of, 799.
 — selenide, 1418.
 — tetrabromide, molecular refraction and dispersion of, TRANS., 299.
 — tetrachloride, molecular refraction and dispersion of, TRANS., 299.
 Silicophosphoric chloride, 815.
 Silicopyrophosphoryl chloride, 1171.
 Silk, yellow, the colouring matter of, and its relation to carotene, 98.
 Sillimanite, synthesis of, 22.
 Silver, action of nitrotyl chloride on, TRANS., 659.
 — allotropic, 266, 803.
 — and lead oxides, compounds of, TRANS., 1093.
 — chloride, action of light on, 1155, 1420, TRANS., 536.
 — — action of, on water when exposed to light, TRANS., 537.
 — — darkened, examination of, for oxygen, TRANS., 543.
 — — decomposition of, by light, TRANS., 536.
 — electrical resistance of, 5.
 — electrolytic separation of, from platinum, 1296.
 — estimation of small quantities of, in lead flux, 1292.
 — fluoride, 1421.
 — influence of, on the freezing point of gold, 1161.
 — lead and zinc, alloys of, 267.
 — native, from the French Congo, 647.
 — nitrate and hydrogen arsenide, reaction between, 1154.
 — occurrence of, in volcanic dust, 277.
 — salts, molecular refraction and dispersion of, in solution, TRANS., 596.
 — subchloride, 1322.
 Silver-zinc alloys, 1158.
 Silver-zinc-bismuth alloys, 1158.
 Slag, basic, detection of foreign raw phosphates in, 109.
 Slags, composition of, 651.
 Sleepers, railway, pickled, estimation of zinc and nitrogen in, 620.
 Snakes, organic basis of shells of eggs of, 236.
 Soap, estimation of cane sugar in, 1558.
 — estimation of resin in, 131.
 Sobrerol, TRANS., 313, 315.
 — inactive, TRANS., 318.
 — preparation of, TRANS., 315.
 Sobrerone, TRANS., 314.
 Soda, caustic, estimation of available soda in, 498.
 — from Vesuvius, 23.
 — total and available, in black ash, estimation of, 497.
 Sodamide, 642.
 Sodium acetate, magnetic rotatory power of solutions of, TRANS., 987.
 — aluminate, analysis of, 365, 864.
 — and potassium sulphates, supposed isomorphism of, 147.
 — benzamide, 58.

Sodium benzenesulphinate and mercaptans, action of iodine on, 924.
 — bisulphide, compound of alcohol with, 1170.
 — butyrate, magnetic rotatory power of solutions of, TRANS., 988.
 — carbonate, dissociation of, 364.
 — — vapour pressure of, 782.
 — chloride, combination of, with ammonia, 643.
 — — effect of, on digestion, 752.
 — — estimation of, in wine, 1398.
 — copper arsenates, 644.
 — — phosphates, 1423.
 — diacetamide, 58.
 — diacetylbenzidine metasulphonate, 313.
 — dibenzamide, 58.
 — ethoxide, saponification by means of, 1143.
 — fluoride, antiseptic properties of, 237.
 — — commercial, analysis of, 498.
 — formate, magnetic rotatory power of solutions of, TRANS., 986.
 — hydrogen carbonate, test for thio-sulphate in, 498.
 — manganites, hydrated, 645.
 — nitrate, estimation of nitrogen in, 107.
 — nitrite, preparation of, 1321.
 — nitroprusside, action of, on animals, 1393.
 — reduction of oxygen compounds with, 150.
 — rhodium nitrite, 809.
 — tungstate, 988.
 — phenylmercaptide, action of, on ethyl chloracetate, 712.
 — preservation and properties of, 982.
 — propionate, magnetic rotatory power of solutions of, TRANS., 987.
 — — thermochemistry of, 1313.
 — pyrophosphite, conversion of, into sodium hydrogen phosphite, 641, 799.
 — salts, magnetic rotation of, PROC., 1890, 142.
 — — molecular refraction and dispersion of, in solution, TRANS., 596.
 — spectrum of, 137.
 — tungstovanadates, 18.
 Soil analyses, 958.
 — analysis of, 959.
 — arable, nitrogenous substance in, 492.
 — containing iron and chromium from the Andaman Islands, East Indies, 958.
 — decomposition of the silicates in, by lime and gypsum, 1135.

Soil, estimation of humus in, 627.
 — peculiar odour of, 858.
 — sandy, behaviour of, towards superphosphate, 105.
 — with ammoniacal solutions, nitrification in, TRANS., 485.
 Soils, bare and cultivated, drainage waters from, 859.
 — estimation of the inorganic constituents of, 622.
 — formation and oxidation of nitrites in, 1545.
 — formation of nitrates in, 1395.
 — loss of nitrates by, 765.
 — nitrification and denitrification in, 101.
 — vegetable, nitrogen compounds in, 610.
 — — volatile nitrogen compounds evolved from, 611.
Soja hispida, composition of the seeds of, 1542.
 Solanidine of potato sprouts, 478.
 Solanine, reaction for, 1562.
Solanum lycopersicum, composition of the fruit of, 956.
 Solubility, augmented, 388.
 — coefficients, determination of, 387.
 — of alkali salts, influence of the hydroxides on, 1318.
 — of gases in water, 384.
 — of mixed salts in water, 795.
 — of mixtures of electrolytically dissociated substances, 142.
 — of some substances in mixtures of water and alcohol, 794.
 Solution, 1412.
 — aqueous, of organic substances, capillary constants of, 1408.
 — deduction from the gaseous theory of, 791, 793.
 — discussion on the theory of, 786.
 — electrolytic theory of, 1405.
 — ideas on, 793.
 — objection raised to the hypothesis of electrolytic dissociation in, 1143.
 — osmotic pressure of salts in, TRANS., 344.
 — The dissociation hypothesis of Arrhenius, 255, 521, 638, 874, 966, 972, 1145, 1405, PROC., 1891, 105.
 Solutions, aqueous cane sugar, cryoscopic behaviour of, 972.
 — association *versus* dissociation in, 972.
 — colloidal, nature of, 1412.
 — dilute aqueous, of electrolytes and non-electrolytes, freezing points of, 971.
 — — cryoscopy of, 971.
 — — kinetic, molecular theory of, 637.

- Solutions, dilute, thermal potential of, 786.
- magnetic rotation of, *Proc.*, 1890, 141.
 - nature of, *Proc.*, 1891, 105—109.
 - of certain salts, variation of density with the concentration of, 254.
 - of double salts, 973.
 - reduction of the results of experiments on, with special reference to the hydrate theory of solution, 973.
 - salt, change of colour of, 1319.
 - specific heats of, 1406.
 - strength of, estimated by their refraction, 1305.
 - sulphuric acid, 973.
 - vapour pressures of, 386.
- Solvents, distribution of a substance between two, 1148.
- Sophora tomentosa*, alkaloid from, 335.
- Sorbinose, estimation of, 1143.
- Sorbitol, d- and l-, configuration of, 1176.
- l-, 668, 1173.
- Sorbose, formation of, from the juice of mountain ash berries, 658.
- Sorghum seed, composition of, 240.
- Sparteine, 842.
- Specific gravities of oxygen, hydrogen, and nitrogen, 1416.
- gravity of a liquid, a function of its boiling point and molecular weight, 780.
 - of frothy syrups, estimation of, 142.
 - of blood in disease, 761.
 - new method of estimating, 1123.
 - of solids, determination of, 11.
 - of sulphuric acid of various degrees of concentration, 150.
 - of viscid substances, determination of, 520, 1147.
 - heat of mercury, 632.
 - heats of some solutions, 1406.
 - inductive capacity of electrolytes, 773.
 - rotatory power of aconitine, *Trans.*, 281.
 - of cane-sugar, action of inorganic salts on, 283.
 - volumes of liquids and their saturated vapours, new method of determining, *Trans.*, 37.
- Spectra, absorption of iodine solutions, 374.
- new method of investigating faint bands in, 773.
 - of blue and yellow chlorophyll, *Trans.*, 106.
 - of coated terminals, 249.
- Spectra of elements of the second periodic group, 935.
- of hydrocarbons, 773.
 - of the alkali metals, 137.
 - relation between the lines of various, 1, 773.
- Spectrometrical constants and chemical constitution of epichlorhydrin, acetaldehyde and paracetaldehyde, and benzene, relation between, 630.
- Spectrum, absorption, of liquid oxygen, 773.
- emission, of the ammonia-oxygen flame, 1305.
 - of oil of turpentine, 2.
 - spark, of gadolinium chloride, 2.
- Spermme, 415, 538, 750.
- identity of, with diethylenediamine, 169.
 - non-identity of, with piperazine, 538.
- Spleen, iron in the, 848.
- Spiegelisen, the carbon of, 646.
- Spirits, analysis of, 503.
- estimation of fusel oil in, 622.
 - influence of extractive matter on the real alcoholic strength of, 865.
- Stachyose, 1446.
- Stannic acid, lakes formed by, 807.
- chloride, vapour pressures and molecular volumes of, *Trans.*, 911.
 - ethide, molecular refraction and dispersion of, *Trans.*, 206.
- Stannous chloride, molecular refraction and dispersion of, in solution, *Trans.*, 596.
- solutions, estimation of free hydrochloric acid in, 241.
- Star-anise, composition of the fruit and seeds of, 957.
- Starch, 33, 284.
- action of potassium permanganate on, 537.
 - conversion of, into dextrin by the butyric ferment, 669, 1446.
 - conversion products of, during germination, 357.
 - estimation of, 127, 865.
 - effect of dissolving in hot glycerol, 165.
 - fermentation of, by the butyric ferment, 660.
 - formation of, from formaldehyde, 1539.
 - formation of, in the grain of wheat, 1285.
 - in leaves, influence of internal causes on the presence of, 604.
 - influence of salt in the formation of, in vegetable organs containing chlorophyll, 856.
 - influence of salt on the quantity

- of, contained in the vegetating organs of *Lepidium sativum*, 1133.
- Starch, new fermentation of, 1284.
- potato, acidity of, 358.
- Starch-grains, action of diastase on, within the plant, 805.
- Steam, dissociation of, 143.
- Stearic acid, α -amido-, 1336.
- α -bromo-, 1336.
- isonitroso-, 541.
- new derivatives of, 1335.
- Stearin, stearic acid, paraffin, and wax, analysis of a mixture of, 1400.
- Steel, detection and estimation of small quantities of aluminium in, 501.
- estimation of manganese in, 963.
- estimation of phosphorus in, 363.
- molecular changes in, 1308.
- passive state of, 250.
- Stereochemistry of the chlorhydrins, 706.

- Succinimide, action of hypobromites on, 1216.
- Succinodiphenyldihydrazine, 1502.
- Sugar, cane-, action of certain inorganic salts on the sp. rot. power of, 283.
- and milk, molecular refraction and dispersion of, in solution, TRANS., 501.
- cryoscopic behaviour of aqueous solutions of, 972.
- estimation of, TRANS., 46.
- estimation of, in soap, 1558.
- inversion of, by hydrochloric acid, 535.
- estimation of, in blood, 218, 504, 1399.
- estimation of, in milk, 127.
- estimation of, in wines, 1557.
- estimation of, in urine, 1559.
- from the pectin of plums, 413.
- fruit-, reduction of, 412.
- grape-, and its isomerides, configuration of, 1173, 1445.
- influence of inactive substances on the rotatory power of, 1178.
- in beetroot, loss of, 108.
- in blood, destruction of, 596.
- effect of medicines, especially of valerian extract, on the destruction of, 754.
- invert, estimation of, in molasses, 760.
- refractive power of, 1000.
- rotatory power of, 1178.
- milk-, estimation of, 1298.
- production of tannin from, in plants, 104.
- raw, estimation of ash in, 127, 1297.
- solubility of, in mixtures of water and alcohol, 536.
- wood-, 659.
- Sugar-beet, experimental plots of, at Grignon in 1890, 493.
- Sugars, action of, in the organism, 1526.
- estimation of, with copper potassium carbonate solution, 125, 1298.
- in mushrooms, 103.
- oximes of, 664.
- present in fungi, 954.
- use of phenylhydrazine for the estimation of, 1143.

Sulpharilic acid, action of carbamide on, 1066.

— action of picric chloride on, *TRANS.*, 717.

Sulphanilide, 569.

Sulphanilidocarbamic acid, 1066.

Sulphates, magnetic rotation of, *PROC.*, 1890, 143.

— titration of, 115.

Sulphides, inorganic, estimation of sulphur in, 107.

— native, formation of, 1434.

Sulphines, aromatic, 714.

Sulphite liquor, 43.

Sulphobenzeneazo-*ar.*-octohydro-*a*-naphthaquinoline, 1260.

Sulphobenzeneazo-*ar.*-octohydro-*β*-naphthaquinoline, 1514.

Sulphobenzeneazotetrahydro-*a*-naphthaquinoline, 1259.

Sulphobenzenediazoamidomethylparatoluidine, 1203.

Sulphobenzenediazoamidotetrahydro-3-methylquinoline, 1255.

Sulphobenzidorthocarboxylic acid, 1058.

Sulphonol, influence of, on proteid metabolism, 1523.

Sulphonamic acids, aromatic, 569.

Sulphonation of quinoline and phenol, 391.

Sulphone derivatives, 1067.

Sulphones, hydrolysis of, 180, 1229.

— stability of, towards alkalis, 1068.

— substituted, 567.

— unsaturated, 1067.

Sulphonic acids, aromatic, method for the isolation of, 1226.

— chlorides, behaviour of, towards thiophenols and thioalcohols in presence of alkalis, 720.

— iodides, aromatic, 718.

— action of zinc ethyl on, 719.

Sulphonio-group, catalytic reduction of, 237.

Sulphoparatoluic acid, ortho-, and its derivatives, 1228.

— anhydride, ortho-, 1229.

Sulphophenylazoethyl-*a*-naphthylamine, 1239.

Sulphophenylazo-*a*-naphthol, para-, 1074.

Sulphophthalic acid, *α*-, 1064.

Sulphur, crystalline form and optical properties of Engel's crystalline modification of, 977.

— dichloride, molecular weight and refractive energy of, 149.

— volumetric estimation of, 617.

— estimation of, 1137.

— estimation of, in copper, 362.

Sulphur, estimation of, in inorganic sulphides, 107.

— estimation of, in iron, 1549.

— estimation of, in pyrites, 496.

— in coal, estimation of, 1137.

— Magnus's "black," 877.

— molecular weight of, in solution, 260.

— "neutral," and metabolism, 1523.

— not combined with hydrogen in illuminating gas, detection of, 862.

— occurrence of in marine muds and nodules, and its bearing on their mode of formation, 994.

— presence and function of, in plants, 606.

— property of, 1416.

— selenium and tellurium, isomorphism of, 1417.

— two new modifications of, 976.

— vapour density of, 881.

Sulphuric acid, action of, on metals, 260.

— free, detection of, in wines, 768.

— free, in chalybeate waters, 1440.

— in natural and plastered wines, 1551.

— mode of combination of, in plastered wines, 768.

— of various degrees of concentration, specific gravity of, 150.

— purification of, for Kjeldahl's process, 617.

— solutions, 973.

— properties of, *PROC.*, 1891, 105.

— volatility of, at ordinary temperatures, 977.

Sulphuric acid chamber exit gases, testing, 497.

Sulphuric anhydride, action of phosphorus on, *TRANS.*, 231.

— compounds of oxides of phosphorus with, *TRANS.*, 230.

Sulphurous anhydride and hydrogen sulphide, estimation of, 498.

— disinfecting powders, analysis of, 124.

— waters, analysis of, 116.

Sulphuryl chloride, function of the chlorine in, *PROC.*, 1891, 60.

— holoxide, 978.

— peroxide, 978.

Superphosphate, behaviour of sandy soil towards, 105.

Superphosphates, Belgian method of estimating the soluble phosphoric acid in, 1289.

— estimation of water in, 110.

— the soluble phosphoric acid compounds of, 880.

Surface, free, of liquids, 1150.
 Surface-tension of the halogens, 257.
 Sweat, excretion of nitrogen in the, 350.
 — of the horse, 349.
 Swedes, digestibility of, 595.
 Sychnodymite, a new cobalt ore, 1167.
 Syrups, frothy, estimation of the specific gravity of, 142.

T.

- Tabernamontana sphaerocarpa*, alkaloid from, 337.
 Tachydrile, synthesis of, 405.
 Taenite, 27.
 Tallow, analysis of, 130.
 — saponification of, 1144.
 Tamarugite, from Tarapaca, 1436.
 Tannic acid of oak wood, 1061.
 Tannin, 70.
 — behaviour of, in plants, 104.
 — conversion of, into benzoic acid, 1481.
 — detection of, in plants, 770.
 — detection of, in urine, 964.
 — estimation of, in hops, 870.
 — estimation of, in tea, 132, 1302.
 — estimation of, in wines, 1399, 1557.
 — extracts, action of phenylhydrazine on, 70.
 — molecular weight of, 146.
 — of algarobilla and myrobalans, 918.
 Tannins, decolorised, manufacture of, 70.
 — origin of, 1395.
 Tantalite from the Black Hills, South Dakota, 886.
 Tartar, analysis of, 372.
 Tartaric acid, combinations of, with potash or soda in solution, 1019.
 — comparison of methods for estimating, 128.
 — constitution of aqueous solutions of, 1018.
 — estimation of, 129.
 — estimation of, in the crude products of tartaric acid factories, 129.
 — estimation of, in wine, 371.
 — free, estimation of, in wines, 1399.
 — inactive, formation of, by the oxidation of phenol, 1020.
 — sensitive reaction of, 867.
 — acids, dextro- and lævo-, thermochemistry of, 969.
 Tartarate solutions, polarisation of certain, 249.
 Tartarates, rotatory dispersion of, 1145.
 — thermochemistry of, 967.
 Tea, amount of theine in, 353.
 — Chinese, examination of, 1302.
 — estimation of caffeine in, 372.
 — estimation of tannin in, 132, 1302.
 — estimation of theine in, 134, 372, 964, 1302.
 Tellurium, detection, separation, and estimation of, 242.
 — sulphur and selenium, isomorphism of, 1417.
 — volumetric estimation of, TRANS., 58, 238.
 Temperature, effect of, on refraction and dispersion, TRANS., 290.
 — influence of, on germinating barley, TRANS., 665.
 — influence of, on refractive power, PROC., 1891, 115.
 — influence of, on the limits of the explosion of gaseous mixtures, 975.
 Temperatures, critical, determination of, 779.
 Terbia, equivalent of, 17.
 Terebenthene, action of aluminium chloride on, 1084.
 — action of bromine on, 1085.
 — amido-, action of phthalic anhydride on, 1086.
 — hydrochlorides, TRANS., 728.
 — oxidation of, in sunlight, TRANS., 311, 315.
 — thermochemistry of, 1315.
 Terebic acid, action of alcoholic ammonia on, 1384.
 — action of aniline on, 1384.
 Terephthalic acid, heats of combustion and formation of, 376.
 — hydro-, heats of combustion of, 1147.
 — acids, bromonitro-, 1056.
 Terpene, a new, 1086.
 — hydrate, molecular refraction and dispersion of, in solution, TRANS., 591.
 — in the oil from compressed gas, 1085.
 Terpenes, 217, 1078, 1240, TRANS., 311, 648, 725.
 — and allied compounds, TRANS., 311.
 — and ethereal oils, 217.
 — general account of the, 1078.
 — olefinic, 655.
 — presence of ethylene linkings in, 464, 1084.
 Terpenylic acid, dry distillation of, 79.
 Terpene dihydrochloride, molecular refraction and dispersion of in solution, TRANS., 591.
 Terpine, 1084.
 Terpinene, 1084.

Tetrabenzylacetonedicarboxylic acid, 674.
 Tetracetyldiamidothymol, 188.
 — acetate, 188.
 Tetracetylthyldiresorcinol, 75.
 Tetradeacylmalonamic acid, 821.
 Tetradeacylmalononic acid, 821.
 Tetradymite from Arizona, 154.
 Tetragalactangeddic acid, TRANS., 1069.
 Tetrahydro-1-amidoquinaldine, 1256.
 Tetrahydrobenzoic acid and its derivatives, 1053.
 Tetrahydrobenzoic acid, Δ^1 , 1481.
 Tetrahydrobenzoic acid, Δ^2 , derivatives of, 1482.
 Tetrahydro-1:3-dimethylquinoline, 1255.
 Tetrahydro-1-methylquinoline, 1253.
 — 3-amido, 1254.
 Tetrahydro-3-methylquinoline, 1254.
 — 1-amido-, 1255.
 Tetrahydro-1-methylquinoline-3-azobenzenesulphonic acid, 1254.
 Tetrahydro-3-methylquinoline-1-azobenzenesulphonic acid, 1255.
 Tetrahydro-1-methylquinolinesulphonic acid, 1257.
 Tetrahydro-1-methylquinoline-3-sulphonic acid, 1257.
 Tetrahydro-3-methylquinolinesulphonic acid, 1257.
 Tetrahydro- β -naphthaquinaldine, 1511.
 Tetrahydro- α -naphthaquinoline, 1253.
 — paramido-, 1259.
 Tetrahydro- β -naphthaquinoline, 1510.
 Tetrahydro- α -naphthoic acid, *ar*-, 1380.
 Tetrahydro- β -naphthoic acid, 1381.
 Tetrahydronaphthylene chlorhydrin, 1072.
 — oxide, 1073.
 Tetrahydronaphthylphenol, 571.
 Tetrahydrophenylmethylfurfuran, properties of, TRANS., 194.
 Tetrahydroquinaldine and benzaldehyde, condensation of, 1102.
 Tetrahydroquinoline, benzyl derivatives of, 88.
 — conversion of, into isatin, 722.
 — homologues of, 1253.
 Tetrahydroterephthalic acid, Δ^1 -, heats of combustion and formation of, 376.
 Tetrahydroxyanthraquinoline, 1240.
 Tetrahydroxyanthraquinone, 935.
 — boiling point of, 1240.
 Tetrahydroxybutanetricarboxylic acid, 547.
 Tetrahydroxydiphthalyl, 1372.
 Tetramethoxydihydrodiphthalyl, 1373.
 Tetramethoxydiphthalyl, 1371.
 Tetrahydroxydiphthalyl-dicarboxylic acid, 1372.

Tetramethoxyquinhydrone, tetrachlor-, 905.
 Tetramethylbenzhydrotricarboxylic acid, 1372.
 Tetramethylbenzidine, 457.
 Tetramethyldiamidochloroethoxyquinone, 904.
 Tetramethyldiamidodiphenyltolylmethane, paranitro-, 727.
 Tetramethyldiamidophenylmethane, action of sulphur on, 189.
 Tetramethylene glycol, 164.
 Tetramethylenedimtramine, 164.
 Tetramethylglutaramidine platinumchloride, 62.
 Tetramethylisocallylene, 997.
 Tetramethylsuccinic acid, 290.
 Tetramethylsuccinimide, 290.
 Tetramethylsuccinophenylimide, 290.
 Tetrammonouprammonium bromide, 399.
 Tetraphenylcrotonolactone, action of alcoholic ammonia on, TRANS., 144.
 — action of methylamine on, TRANS., 147.
 Tetraphenylpyrrolone, reduction of, TRANS., 145.
 Tetrapropylglutaramidine derivatives, 62.
 Tetrapropylsuccinimidine salts, 87.
 Tetrarabinantrigalactangeddic acid, TRANS., 1035.
 Tetrathiocarbamidammonium bromide, TRANS., 384.
 — chloride, TRANS., 386.
 — iodide, TRANS., 385.
 Tetrazodiphenyl, 570.
 Tetrazodiphenyldisulphonic acid, 930.
 Tetrazotic acids, 1038.
 Tetrethoxyquinhydrone, tetrachlor-, 905.
 Tetrethyl parachloroquinonedimalonate, 455.
 — paradichloroquinoldimalonate, 455.
 — paramidoquinonedimalonate, 455.
 Tetrethylacetonedicarboxylic acid, 674.
 Tetrethylammonium bromide and iodide, compounds of with thiocarbamide, TRANS., 387.
 Tetrethylamidophenylditolylmethane, nitro- and amido-derivatives of, 728.
 Tetrethylglutaramidine platinumchloride, 62.
 Tetrethylsuccinamidine hydrochloride, 37.
 Tetrethylsuccinimidine hydrochloride, 37.
 Tetric acid, 1182, 1187.
 — — and its homologues, 1187.
 Tetrole-rings, constitution of, 1195.
 Thallium, action of nitrosyl chloride on, TRANS., 657.
 — chlorochromate, 1422.

- Thallium chromate, reactions of, 1422.
 — estimation of, 1295.
 — iodide, solubility of, 1295.
 — potassium sulphide, action of hydrogen on, 16.
 Thebaine, physiological activity of, 762.
 Theine, amount of, in tea, 358.
 — estimation of, in tea, 134, 372, 964, 1302.
 Thermal expansion, method of determining, for equal quantities of heat, 142.
 — potential for dilute solutions, 786.
 Thermochemistry of aspartic acid, malonic chloride, and tartrates, 967.
 — of bibasic organic acids, 968.
 — of dextro- and lævo-tartaric acids, 969.
 — of fats and fatty acids, 11.
 — of humic acid from sugar, 1456.
 — of organic chlorine compounds, 1310.
 — of platinum chloride and its compounds, 966.
 — of products of oxidation of uric acid, 1448.
 — of propionic acid and alkali propionates, 1313.
 — of the camphene series, 1313.
 Thermochemistry. See also Heat.
 Thermometer, platinum, determination of boiling and freezing points by means of, 251.
 Thermometers of Jena glass, rise of the zero point of, 8.
 — platinum, standardising, 1146.
 Thernonatriite from Vesuvius, 23.
 Thiamides, action of aldehydes on, 831.
 — action of alkylene bromides on, 701.
 — action of ethylenediamine on, 1003.
 Thianhydro-compounds, formation of, 1048.
 Thiazole, μ -bromo-, 745.
 — μ -chloro-, 745.
 Thiazole- α -carboxylic acid, μ -amido-, 743.
 Thiazole-derivatives from bromopyruvic acids and from ethyl bromoacetate, 742.
 Thiazole-dicarboxylic acid, μ -amido-, 224.
 Thiazoles, 220.
 — nitroso-derivatives of the, 1515.
 Thiazole-series, diazo-compounds of the, 225.
 Thiazoletriazole, 1516.
 Thiazole-yellow, 195.
 Thiazoline, μ -nitrosoimido-, 1515.
 Thiazylacetic acid, μ -amido-, 743.
 Thiényloximidoacetic acid, β -, 444.
 Thiénylphenylketoximes, 446.
 Thioaldehydes, aromatic, 1050.
 Thiocarbamide and methyl- and ethylammonium salts, TRANS., 391.
 Thiocarbamide, benzyl derivatives of, TRANS., 551.
 — compound of triethylammonium bromide with, TRANS., 390.
 — compound of, with diethylammonium bromide, TRANS., 389.
 — compounds of, with ammonium haloid salts, TRANS., 384.
 — compounds of, with tetrethylammonium bromide and iodide, TRANS., 387.
 — constitution of, 548, TRANS., 394.
 — methylene derivatives of, 1339.
 — new additive compounds of, TRANS., 383.
 Thiocarbamides, 1474.
 — action of hydroxylamine, ethoxylamine, and benzyloxylamine on, 558.
 — aromatic, preparation of, TRANS., 196.
 — substituted, action of acetic anhydride on, TRANS., 396.
 — — and ammonium bromide, TRANS., 386.
 Thiocarbethamidophenol, 53.
 Thiocarbimides, action of, on hydroxylamine, 1222.
 Thiocarbomethylorthamidophenol, 54.
 Thiocarborthamidophenol, 52, 53.
 Thiocyanamidocinnamic acid, orthometa-, 199.
 Thiocyanates, alkali, decomposition of, 1170.
 — metallic, electrolysis of, 1170.
 Thiocyanic acid, reaction of, 128.
 Thiocyanopropylphthalimide, 1473.
 Thioflavin, 195.
 Thionyl bromide, 716.
 Thionylamines, 810, 715.
 Thionylaniline, 810, 715.
 Thionylbenzidine, 717.
 Thionylechloranilines, 717.
 Thionylethylamine, 718.
 Thionylmethylaniline, 74.
 — nitroso-, 74.
 Thionylnitranilines, 717.
 Thionylorthotoluidine, 717.
 Thionylphenylhydrazones, 717.
 Thionyltribromaniline, 717.
 Thiophen, behaviour of, with phenylhydrazine, 1342.
 Thiophenic acid, α -, heats of combustion and formation of, 376.
 Thiophens, brominated, oxidation products of, 427, 393.
 Thiosulphate, test for, in sodium hydrogen carbonate, 493.
 Thiosulphates, 879.
 Thiosulphonates, action of phosphoric chloride on, 927.
 Thiosulphonic acids, aromatic, 719.
 — — — action of reagents on, 719.

- Thiosulphonic acids, aromatic, and aliphatic, 926.
- Thiosulphonic acids, aromatic, thioanhydrides of, 924.
- Thiouramidocinnamic acid, ortho-, 198.
- para-, 199.
- Thiouramidoximes, condensation products from, 560.
- Thiouvinuric acid, 742.
- Thiovanadates, 989.
- Thioxanthone, 1058.
- Thorium dioxide, action of magnesium on, 802.
- hydride, 802.
- Thymol, 899.
- hygroscopic behaviour of, 1497.
- orthobromo-, 899, 900.
- test for, 370.
- Thymol-derivatives, constitution of, 46, 188.
- Thymolorthosulphonic acid, parabromo-, potassium salt of, 899.
- salts of, 899.
- Thymolparasulphonic acid, orthobromo-, 899.
- Thymoquinone, 2-bromo-, 899.
- dioxime, 297.
- Thymoquinone-derivatives, constitution of, 47, 297.
- Thymyl acetate, dinitro-, 47.
- benzoate, dinitro-, 46.
- Timbo, poisonous constituents of, 938.
- Timboin, 938.
- Timbole, 939.
- Tin, action of nitrosyl chloride on, TRANS., 661.
- and antimony, separation of, 366.
- detection and estimation of, in corpses, 121.
- gold, and cadmium, freezing point of triple alloys of, TRANS., 936.
- ores, dry assay of, 247, 502.
- oxide, action of magnesium on, 802.
- Tin-lead alloys, melting points of, 641.

- metachloropara-, 1466.
- ortho-, ortho- and para-nitro-derivatives of, TRANS., 1013.
- ortho-, sulphonation of, 1490.
- orthonitrometa-, 187.
- orthonitro-ortho-, reduction of, in alkaline solution, TRANS., 1015.
- para-nitro-ortho-, reduction of, in alkaline solution, TRANS., 1015.
- thionylpara-, 310.
- Toluidines, nitro-ortho-, displacement of the amido-group in, by chlorine, TRANS., 1017.

Toluidines, ortho- and para-, compounds of metallic sulphites with, 1081.
 — ortho-, para- and ortho-nitro-, reduction of, in acid solution, TRANS, 1016.
 Toluidinemetasulphonic acid, ortho-, 1490.
 — para-, 1490.
 Toluidobenzoic acid, metamidopara-(ortho), 306.
 — (para)-, 306.
 — metanitropara(ortho)-, 306.
 — (para)-, 306.
 Toluidoethylphthalimide, ortho-, 1207.
 — para-, 1207.
 Toluidotricarballylic acid, ortho-, 680.
 Toluquinaldine, ortho-, oxidation of, 1093.
 Toluquinoline, amidopara-, 325.
 — amidortho-, 327.
 — nitro-ortho-, 327.
 — nitropara-, 325, 327.
 — orthamidochloropara-, 327.
 — orthamidopara-, 327.
 — orthonitropara-, 327.
 Toluylyl isocyanate, meta-, 201.
 Toluylohlorisquinoline, meta-, 202.
 Toluleyanocamphor, ortho-, 1499.
 Toluyldioxamide, 908.
 Toluylenamidinedimethoxybenzenyl-carboxylic acid, 746.
 Toluylenediamine, dinitrometa-, 192
 — physiological action of, 1281.
 Toluylenediaminebenzylidenesulphonic acid, meta-para-, sodium salt of, 721.
 Toluylenedimethoxyphthalamidone, 746.
 Toluylenedioxamethane, 907.
 Toluylenedioxamic acid, 908.
 Toluylnitromethane, meta-, 201.
 Toluylythiamide, ortho-, 701.
 — para-, 702.
 Tolyl ethyl ketone, para-, and its nitro-derivatives, 1052.
 — methyl ketone, para-, derivatives of, 1021.
 — — — oxidation of, 1364.
 — naphthyl sulphides, 1238.
 — phenyl ketone, para-, stereochemical isomerides of, 68.
 Tolylacetic acid, para-, metanitro- and dinitro-, 1365.
 — preparation of, 1365.
 Tolylallylsulphide, ortho-, 550.
 — para-, 550.
 Tolylallylsulphone, para-, 1067.
 Tolylazoparacetol, para-, 214.
 Tolylazoparacetol, ortho-, 213.
 Tolylazophenetol, ortho-, 212.
 — para-, 212.
 Tolylazophenol, ortho-, 212.

Tolylazorthocresol, ortho-, 212.
 — para-, 213.
 Tolylbenzyloxythiocarbamide, ortho-, 558.
 Tolybromacetic acid, para-, 1366.
 Tolyeyanamide, ortho-, 558.
 Tolyldihydrotolutriazine, para-, 841.
 Tolyldisazophenol, ortho-, 212.
 Tolyldisazorthocresol, ortho-, 212.
 — para-, 213.
 Tolyglycocine, para-, fusion of, with alkalis, 928.
 Tolylydrazoparacetol, para-, 214.
 Tolylydrazoparacetol, ortho-, 213.
 Tolylydrazophenetol, para-, 212.
 Tolylydrazorthocresol, para-, 213.
 Tolyhydroxythiocarbamide, ortho-, 558.
 Tolylimido uethylene ethylene bisulphide, para-, 895.
 Tolyindigo, ortho-, 837.
 Tolyisoquinoline, 202.
 Tolylmethylbenzylhydroxypyrimidine, para-, 470.
 Tolylmethylethylhydroxypyrimidine, para-, 469.
 Tolylmethylpyrazoloneketoparatolylhydrazone, para-, TRANS, 340.
 Tolyloorthophenylenguanidine, para-, 1470.
 Tolyloorthotoluyleneguanidine, para-, 1470.
 Tolyloxamethane, amido-, 907.
 Tolyloxamic acid, amido-, 833.
 Tolyloxamide, amido-, 834.
 Tolyloxanilide, amido-, 834.
 Tolyphenylhydroxypyrimidine, para-, 470.
 Tolyphenylketoxime, meta-, 1480.
 — ortho-, 1480.
 Tolylopyridine, 1-para-, 1244.
 Tolylopropylene, β -para-, 1021.
 Tolylopropylenepseudosennithiocarbamide, ortho- and para-, 550.
 Tolylothiazoline, μ -ortho-, 701.
 — para-, 701.
 Tolylothiocarbamide, para-, action of acetic anhydride on, TRANS, 403.
 Tolylothiocarbamide, meta-, preparation of, TRANS, 403.
 — ortho-, preparation of, TRANS, 402.
 — para-, preparation of, TRANS, 404.
 Tomatoes, composition and anatomical structure of the fruit of, 955, 956.
 Tourmaline, chemical nature of, 21.
 Toxalbumin secreted by the microbe blennorrhagic pus, 1521.
 Toxicological observations, 772.
 — investigations, detection of mercury in, 844.
 Transfusion of mixtures of blood and salt solution, 317.

- Trees with red leaves, chlorophyllic assimilation of, 102.
 Trehalose, 1000.
 — in mushrooms, 103.
 Triacetic acid, δ -lactone of, TRANS., 607.
 — — — action of bromine on, TRANS., 612.
 — — — reactions of, TRANS., 614.
 Triacetin, preparation of, 1183.
 Triacetyldiamidothymol, 188.
 Triacetylenyltetramidotoluene, 192.
 Triacetylgallamide, 1220.
 Triacetylgentisein, 1244, 1886.
 Trianisin, 708.
 Triarabinantrigalactangeddic acid, TRANS., 1071.
 Triarabinantrigalactangeddic acid, TRANS., 1087.
 Triazine-derivatives, nomenclature of, TRANS., 679.
 Triazines, nitro-, reduction of, TRANS., 701.
 — substituted, preparation of, TRANS., 679.
 Triazine-series, TRANS., 678.
 Triazobenzene, 696.
 Tribenzamide, 58.
 Tribenzoïn, 708.
 Tribenzoylpropane, 1 : 2 : 3-, 681.
 Tribenzyl phosphate, 1015.
 Tribenzylamine, action of bromine on, 189.
 — boiling point of, 1240.
 Tribrassinidin, heats of combustion and formation of, 11.
 Tricalcium phosphate, action of, on monocalcium phosphate, 880.
 Tricarballic acid, 680.
 — new synthesis of, 423.
 Tricarballoylorthotoluidic acid, 680.
 Tricarballoylphenylhydrazidic acid, 680.
 Trioresotin, 708.
 Tricyclic systems, reduction of, 1258.
 Tridymite, preparation of, 22.
 Trierucin, heats of combustion and formation of, 11.
 Triethoxybutane, 285.
 Triethoxypropane, 285.
 Triethyl aconitoxalate, 424.
 Triethylamine, action of, on diisobutylamine oxalate, 377.
 — molecular refraction and dispersion of, TRANS., 295.
 Triethylammonium bromide, compound of thiocarbamide with, TRANS., 890.
 Triethylenetetramine, 414.
 Triethylisoxazole, TRANS., 432.
 Triethylsulphine, derivatives, molecular refractive energy of, 1303.
 Trigalactangeddic acid, TRANS., 1048.
 Triglycerides of aromatic acids, 708.
 Trihydrazine dihydriodide, 264.
 Trihydroxyalizarin-blues, 1382, 1388.
 Trihydroxyanthraquinoline, 1210.
 Trihydroxybenzenes, formation of tannins from, 1395.
 Trihydroxyglutaric acid, inactive, 1177, 1446.
 Trihydroxytetrahydrobenzoic acid, 920.
 Trilaurin, heats of combustion and formation of, 11.
 Trimerite from Sweden, 404.
 Trimethylacetaldehyde, 998.
 Trimethylacetoneitrile, polymeride of, 1170.
 Trimethylamine carbonyl iodoplatinit hydriodide, 1164.
 Trimethylcarbinol, 998.
 Trimethylene, action of chlorine on, 159.
 — chloro-, and some allied compounds, reaction capacity of, 888.
 — cyanide, imidoethers from, 61.
 — — molecular refraction and dispersion of, TRANS., 295.
 — dichloro-, and its dibromide, 159.
 — diphenyl ether, 1468.
 — iodide, molecular refraction and dispersion of, TRANS., 295.
 — mono- and di-chloro-, action of bromine on, 888.
 — phenyl ethyl ether, 1468.
 — relation between the spectrometrical constants and chemical constitution of, 681.
 Trimethylenediethylsulphone, 181.
 Trimethyleneditolylsulphone, 1220.
 Trimethylethyl alcohol, 998.
 — trimethylacetate, 998.
 Trimethylethylene, halogen derivatives of, 888, 810.
 Trimethylgallamide and its reduction, 1218.
 Trimethylgallyl alcohol, 1219.
 Trimethylguanidil, 580.
 Trimethylisoxazole, TRANS., 418, 429.
 Trimethylparaphenylonediamine, 1032.
 Trimethylsuccinic acid, 828, 1016.
 — — and dimethylglutaric acid, relative properties of, 669.
 — acids, stereoisomeric, 669.
 Trimethylthiazole, 228.
 Trimethylxylidylammonium iodide, 1205.
 Trimyristin, heats of combustion and formation of, 11.
 Triphenyl-1-2-hydronaphthazonium hydroxide, [1-2-3-], 1169.
 Triphenylmethane and its homologues, hydroxy-nitro-derivatives of, 1378.
 Triphenylmethane-group, dyes of the, 727.
 Triphenylmethaneorthocarboxylic acid, 1462.

Triphenylthiazole, 222.
 Triphenyltriamidobenzene, nitroso-, 190.
 Triphenyltrinitrophenol, 1026.
 Tripropylamine, molecular refraction and dispersion of, TRANS., 296.
 Triquinylcarbinol, 1106.
 Triquinylmethane and its derivatives, 1106, 1262.
 Triacyclin, 708.
 Tritetrahydroquinaldylmethane, 1103.
 Trithionyl, 427.
 — hexabromide, 428.
 — tribromo-, 428.
 Trithienyltrisulphonic acid, 428.
 Tritolyltriamidobenzene, nitrosotripara-, 190.
 Tritopine, 227.
 Troilite, synthesis of, 990.
 Tropic acid, 749.
 Tropidine and its bromo-derivatives, 90.
 Tropine, 1121.
 — allocinnamate, 833.
 — aurochloride, 1121.
 — cinnamate, 833.
 — mercuriochloride, 1122.
 — oxidation products of, 749.
 Truxillie acids, amido-, 1496.
 — nitro-derivatives of, 1495.
 Trypsin, influence of temperature on, 1271.
 Tryptic enzymes, gelatin as a reagent for the detection of, 1523.
 Tuberculin, proximate analysis of, 1283.
 Tungstates, action of platonic hydroxide on, 1323.
 Tungston, new oxygen compound of, 988.
 Tungstovanadates, 18.
 Turkey-red oil, 542, 665.
 — — — estimation of fatty matter in, 1560.
 Turpentine, TRANS., 725.
 — action of hydrogen chloride on, TRANS., 728.
 — detection of petroleum in, 217.
 — estimation of, in paints and varnishes, 1302.
 — hydrochloride, conversion of, into camphono hydrochloride, TRANS., 730.
 — increase of rotatory power of, on keeping, TRANS., 726.
 — sp. rot. power and sp. gr. of, 217.
 — oil of, detection of, in essence of lemons, 1497.
 — — — oxidation of, in sunlight, TRANS., 311, 315.
 — oils, TRANS., 311.
 Tylophora *asthmatica*, alkaloid from, 1266.
 Tylophorine, 1207.

Tyrosine, condensation of, with benzene-sulphonic chloride, 203.

U.

Ulexine, 946.
 — and cytosine, differences between, 334.
 Ultramarine, artificial, discovery and early manufacture of, 400.
 Umanganite from the Argentine, 1435.
 Umbelliferoneacetic acid, β -, 672.
 Uramidocinnamic acid, ortho-, 198.
 Uramidotyloxamethane, 908.
 Uramidotyloxamic acid, 834.
 Uramidotyloxamide, 908.
 Uraninite, occurrence of nitrogen in, 527.
 Uranium, detection of minute quantities of, 360.
 — selenites, 262.
 Urea, acetate, 1443.
 — elimination of, in fever, 1530.
 — estimation of, 132, 133, 759, 1561.
 — estimation of, in urine, 512.
 — excretion of, in liver diseases, 758.
 — influence of muscular work on the output of, 350.
 — rapid method of estimation of, in urine, 133.
 — the soluble ferment of, 100.
 Urcides from normal acids, 1448.
 Urethanotyloxamic acid, 834.
 Uric acid, estimation of, in urine, 1297.
 — excretion of, in cases of leucamia, 483.
 — — formation of, in the animal organism, 1340.
 — — influence of drinking large quantities of water on the excretion of, 848.
 — — products of the oxidation of, 1448.
 — — salts, artificial formation of sphaeroliths of, 760.
 Uric acid-group, azines of, 1341.
 Urine, bacterial, detection of albumin in, 136.
 — calcium salts in, 484.
 — carbohydrates in, 1392.
 — detection of acetone in, 624.
 — detection of bile constituents in, 135.
 — detection of tannin in, 964.
 — detection of urochloralic acid in, 624.
 — diastatic ferment in, 760.
 — estimation of acetone in, 370.
 — estimation of iodine in, 1288.
 — estimation of phosphoric acid in, 619.

Urine, estimation of sugar in, 1559.
 — estimation of urea in, 512.
 — estimation of uric acid in, 1297.
 — estimation of urobilin in, 1278.
 — excretion of balsams in, 600.
 — hæmatoporphyrin in, 601, 1130, 1279.
 — human, nitrogenous substances in, 1277.
 — in a case of melanotic sarcoma, 484.
 — indigo red (indirubin) in, 850.
 — influence of the administration of acids and alkalis on the reaction of, 1528.
 — normal, proteid in, 1130.
 — optical estimation of albumin in, 1403.
 — passage of naphthol into, 98.
 — rapid method of estimating urea in, 133.
 — unusual pigment in, 601.
 — volumetric estimation of albumin in, 627.
 — volumetric estimation of chlorides in, 495.
 — xanthine substances in, 1528.
 Urobilin, estimation of, in urine, 1278.
 — in various diseases, 1278.
 Urochloralic acid, detection of, in urine, 624.
 Uropepsin, 483.
 Uro-phosphates, 98.
 Uroptyalin, 483.
 Urotrypsin, 483.
 Utabite from New Mexico, 274.

V.

Valeria officinalis var. *angustifolia*, 230.
 Valerian extract, effect of, on the destruction of sugar in the blood, 754.
 Valeric acid, β -amido-, from the putrefaction of proteids, 948.
 — diisonitroso-, 417.
 Vanadic acid, estimation of, in vanadotungstates, 247.
 Vanadotungstates, estimation of vanadic acid in, 247.
 Vanadium fluorides, 884.
 Vapour densities, determination of, 635.
 — density, experiments on, 253.
 — of ammonium chloride, 1407.
 — of sulphur, 381.
 — pressure, constant, 781.
 — of a mixture of two volatile liquids, 1407.
 — of copper potassium sulphate chloride and its solutions, 783.

Vapour pressure of water up to 200 atmospheres, 1407.
 — pressures of acetic acid, TRANS., 903.
 — of carbon tetrachloride and stannic chloride, TRANS., 911.
 — of dibenzyl ketone, TRANS., 626.
 — of homologous compounds, 969.
 — of mercury, TRANS., 629.
 — of solutions, 386.
 — of some aqueous salt solutions at 0°, 783.
 Vapours, dissociation of, by the silent discharge, 143.
 — refraction and chemical constitution of, 629.
 — saturated, new method of determining the specific volumes of, TRANS., 37.
 Varnishes, estimation of turpentine in, 1302.
 Vaseline, estimation of fats in, 1401.
 Vegetable-cell membranes, chemical composition of, 238.
 Vegetable-organism, action of yeast on, 237.
 Vegetables, estimation of pentoses in, 768.
 Velocity coefficients of bases, 1413.
 — of lactone formation in the case of certain hydroxy acids, 822.
 — of reaction between bromic and hydriodic acids, influence of mineral acids on, 144.
 — between metals and halogens, 1149.
 — in gelatin, 638.
 — of the halogenisation of fatty hydrocarbons, 145.
 Veratrine, 585.
 — reaction for, 1562.
 Veratroidine, 87.
 Veratronitrile, 712.
Veratrum album, alkaloids of, 87.
 — alkaloids of the rhizome of, 230.
 Vertebrates, relative alkalinity of blood of, 348.
 Vesuvian, composition of, 651.
Vicia faba, artificial infection of, with *Bacillus radicicola*, 1539.
 — *sativa*, composition of the seeds of, 1542.
 Viciæ in seeds, 490.
 Vinyl alcohol, heat of combustion of, 633.
 Violan and autochroite, identity of, 407.
 Viscid substances, determination of the sp. gr. of, 520, 1147.

Viscosity of liquid carbon compounds and its relation to chemical constitution, 380.
 Vitellin, crystalline, 342.
 Vitelloses, 342.
 Vivianite, curious occurrence of, 156.
Voacanga fatida, alkaloid from, 337.
 Volcanic dust, occurrence of silver in, 277.
 Volumes, molecular. See Molecular volumes.
 — specific. See Specific volumes.
 Volumetric analysis, the true or Mohr's litre for, 1548.

W.

Walpewite from the Ural, 531.
 Water and alcohol, solubility of some substances in mixtures of, 794.
 — determination of the critical temperature and pressure of, 779.
 — distilled, detection of traces of copper in, 620.
 — estimation of, in butter, 1300.
 — estimation of, in minerals, 766.
 — estimation of, in superphosphates, 110.
 — estimation of oxygen dissolved in, 616.
 — estimation of the hardness of, 1554.
 — examination of, for contamination by gas-works, 117.
 — expansion of, 8.
 — hot, compressibility of, 634.
 — solvent action of, on glass, 634.
 — measurement of the quantity of light that enters, 2.
 — mineral, of Penon de los Banos, Mexico, 279.
 — of crystallisation, influence of, on the electrical conductivity of salt solutions, 141.
 — recognition of the neutrality of, 1136.
 — refractive indices of, 629.
 — sea, diffusion of fresh water into, 970.
 — vapour pressure of, up to 200 atmospheres, 1407.
 — volumetric composition of, 976.
 Waters, chalybeate, containing free sulphuric acid, 1440.
 — drainage, composition of, 765.
 — from bare and cultivated soils, 859.
 — from hot springs in Ferguson Island, 280.

Waters, mineral, estimation of free and combined carbonic anhydride in, 862.
 — estimation of lithium in, 1292.
 — natural, estimation of hardness of, 116.
 — potable, estimation of nitrates in, TRANS., 320.
 — estimation of nitric and nitrous acids in, 496.
 — sulphurous, analysis of, 116.
 Wax, complete chlorination of, 812.
 — paraffin, stearin and stearic acid, analysis of a mixture of, 1400.
 — white, composition of, 625.
 Wernerite from Chili, 1438.
 Wheat, Bordeaux, analyses of, 1286.
 — cultivation of, in a sterile siliceous soil, 104.
 — development of, and formation of starch in the grain, 1285.
 Wheat-bran, arabinose from, 33.
 Wine, detection of artificial coloration in, 1563.
 — detection of nitrates in, 961.
 — detection of nitric acid in, 1551.
 — estimation of dissolved solids in, 123.
 — estimation of hydrogen potassium tartrate, free tartaric acid, malic acid, and mineral salts in, 371.
 — estimation of malic acid in, 128.
 — estimation of sodium chloride in, 1398.
 — fig-, 1185.
 — volumetric estimation of glycerol in, 369.
 Wine- lees, analysis of, 372.
 Wines, analyses of, 359.
 — detection of free sulphuric acid in, 768.
 — estimation of sugar and tannin in, 1557.
 — estimation of tannin and free tartaric acid in, 1399.
 — extraction of the colouring matter of, 1563.
 — natural and plastered, sulphuric acid in, 1551.
 — plastered and mixed with sulphuric acid, distinction between, 123.
 — condition of the sulphuric acid in, 123.
 — mode of combination of sulphuric acid in, 763.
 Wood-gum, 659.
 Wood-sugar, 659.
 Wool, influence of, on the material exchange in sheep, 1392.
 Work, muscular, and proteid metabolism, 596. 847.

Wort, analysis of, 368.
Wurtzite, synthesis of, 990.

X.

Xanthine bases, formation of the animal organism, 1340.
Xanthines in urine, 1528.
Xanthoxalanil, 902.
Xanthoxalotoluidil, 903.
Xenotime, occurrence of, as an accessory constituent of rocks, 993.
Xylalphthalide, dinitro-, 201.
— meta-, 200.
— nitro-, 201.
Xylalphthalimidine, meta-, 201.
— nitro-, 201.
Xylan, 659.
Xylene, commercial, occurrence of ethylbenzene in, 1197.
— 3:6-diamido-4:5-dichlorortho-, 1201.
— dinitrobromometa-, 1245.
— 3:6-dimtro-4:5-dichlorortho-, 1201.
— ortho-, chlorobromo-, nitro-derivatives of, 921.
— derivatives of, 921.
Xylenecinnamene, meta-, 207.
— ortho-, 207.
— para-, 207.
Xylenedisulphonethylamide, meta-, 74.
Xylenedisulphonic acid, bromo-, 74.
— chloro-, 74.
— para-, and its derivatives, 1374.
Xylenes, molecular refraction and dispersion of, TRANS., 295.
Xylenesulphonic acid, meta-, 73.
— iodo-, 73.
Xylidine, adjacent, ortho-, 1203.
— α -meta-, compounds of metallic sulphides with, 1031.
— meta-, nitration of, 692.
Xylidines, ortho-, nitration of, 692.
Xyloethylphthalimide, 1208.
Xylitol, 668.
Xyonic acid, 668.
Xylo-3:6-quinol, 4:5-dichloro-, 1201.
Xyloquinoline, amidometa-, 328.
— nitrometa-, 328.
Xylo-3:6-quinone, 4:5-dichloro-, 1201.
Xylose, 659, 667.
— configuration of, 1175, 1446.
— estimation of, 1143.
— from Maize cobs, 1001.
Xylol ethyl ketone, meta-, 564.
— methyl ketone, 4-chlorometa-, 912.
— para-, 1053.
Xylantipyryne, 1363.
Xylol-2:3-dimethylpyrazolone, α -meta-, 1363.

Xylylene bromide, ortho-, action of ammonia on, 1353.
Xylglycollic acid, meta-, 564.
— para-, 564.
Xylglyoxylic acid, meta-, 564.
Xylhydrazino, α -meta-, 1362.
Xylmethylpyrazolone, α -meta-, 1363.
Xylthiocarbimide, meta-, preparation of, TRANS., 405.

Y.

Yeast, action of hydrogen fluoride and of fluorides on, 1532.
— action of, on the animal and vegetable organism, 237.
— apparatus for the manufacture of pure, 352.
— metaphosphoric acid in the nuclei of, 477.
— pure, manufacture of, 1532.
Yttrium hydride, 1157.
Yttrium-earths, separation of, 1425.
Yttrium-group, earths of the, 984.

Z.

Zero, absolute, determinations to test the validity of Person's, 519.
Zinc, action of nitrosyl chloride on, TRANS., 556.
— and manganese, separation of, 963.
— carbonate and silicate, estimation of, in calamine containing lead, 863.
— chemically pure, cause of the slight solubility of, in acids, 983.
— chloride, action of ammonia on, 1157.
— chromites, basic, 987.
— electrical resistance of, 5.
— electrolytic estimation of, as amalgam, 1553.
— estimation of, in pickled railway sleepers, 620.
— ethyl, action of liquid carbonic anhydride on, 288.
— molecular refraction and dispersion of, TRANS., 296.
— metallic, estimation of, in zinc dust, 563.
— propionate, formation of, by the action of carbonic anhydride on zinc ethyl, 288.
— selenites, 262.
— spectrum of, 1.
— sulphate, new variety of, 992.
— sulphide, behaviour of preparations of, 881.
— new variety of, 154.
— sulphite, basic, 1157.

Zinc tannate, 70.
 — volumetric estimation of, 112.
 Zinc-bismuth alloys, 1158.
 Zinc-lead-tin alloys, 267.
 Zinc-silver alloys, 1158.
 Zinc-silver-bismuth alloys, 1158.
 Zinc-silver-lead alloys, 267.
 Zinc-tin-bismuth alloys, 1158.

Zircon from Australia, 1169.
 — from North Carolina, 155.
 Zirconates of the alkalis and alkaline
 earths, 1431.
 Zirconic anhydride, action of magnesium
 on, 802.
 Zirconium hydride, 802.

ERRATA.

VOL. LVIII (Abstr., 1890).

Page	Line	
1002	11	from bottom, for " $(C_5NH_3Me)_2, H_3PtCl_6$ " read " $(C_5NH_3Me)_2, H_3PtCl_6$."

700	2	" top, "	"metahydrobenzylazoximethenyl" read "meta- hydroxybenzenylazoximethenyl."
748	13	" " "	"benzene" read "benzol."
749	25	" bottom, et seq., for	"tropinic acid" read "tropic acid."
777	10	" " "	" "carbonic oxide" read "carbonic an- hydride."
777	bottom,	for	"gas" read "steam."
828	21	" top, "	"Methacrylic" read "Methacrylic."

VOL. LX (Abstr., 1891).

Page	Line		
870	6	from top,	for "his own" read "his own*" and insert footnote " * Lewkowitsch has replied to this criticism in <i>J. Soc. Chem. Ind.</i> , 9, 812; see this vol. p. 511, line 8 <i>et seq.</i> "
905	12	" "	" <i>Tetrachlorotetretroxyquinonehydrone</i> " read " <i>Tetrachlorotetretroxyquinhydrone</i> ."
918	3	" bottom,	The formula for ellagotannic acid should read " $C_6H_2(OH)_2 \cdot CO \cdot O \cdot C_6H_2(OH)_2 \cdot COOH$."
946	20	" top,	for "[2] 29" read "329."
955	24	" bottom,	" "G. BRISST" read "G. BRIOSI."
962	20	" "	" "F. HOFMEISTER" read "E. LUDWIG and E. TILNER."
989	top,	"	" <i>hypertungstates</i> " read " <i>pertungstates</i> ."
"	2	" top,	" <i>hypermolybdates</i> " " <i>permolybdates</i> ."
999	18	" "	" " $C_nH_{2n+2}O_3$ " read " $C_nH_{2n-2}O_3$."
1213	20	" bottom,	" <i>Methylrosindulone</i> " read " <i>Methylrosindulone</i> ."
1287	5	" top,	" <i>phenylglucosazone</i> " read " <i>phenylglucosazone</i> ."
1312	23	" "	" " $C_6H_7NaO_4$ " read " $C_6H_9NaO_4$."
1313	12	" "	" " $C_6H_3O_2$ " read " $C_6H_2O_2$."
"	19	" "	" "27" read "20·7."
1315	14	" bottom,	" "418·6" read "+ 18·6."
1346	26	" top	" <i>Metanitrodioxytri-</i> " read " <i>Metanitrodihydr-</i> <i>oxytri-</i> ."
1417	8 and 9	" bottom.	" "a new gaseous compound, <i>phosphorus sulpho-</i> <i>fluoride</i> , PF_3S " read "a gaseous compound, thiophosphoryl fluoride, PF_3S (see Thorpe and Rodger, <i>Trans.</i> , 1888, 766; and 1889, 806)."
1480	4	" top,	" " <i>Parahomobenzhydrylaminethiocarbamide</i> " read " <i>Parahomobenzhydrylthiocarbamid-</i> ."
1522	15	" "	" "J. MOITHESSIER" read "G. MOITHESSIER."
1535	Table.	The calcium	The calcium nitrate was added to pot 10 <i>only</i> , the ammonium sulphate to pot 12 <i>only</i> ; pots 9 and 11, as stated in the text, were control pots to which nothing was added.
